The lumen-apposing metal stent (LAMS)-in-LAMS technique as an intraprocedural rescue treatment during endoscopic ultrasound-guided gastroenterostomy

Endoscopic ultrasound-guided gastroenterostomy (EUS-GE) is a new effective mini-invasive treatment for gastric outlet obstruction (GOO) [1–3]. An anastomosis is created between the stomach and a duodenal (or jejunal) loop by placement of a lumen-apposing metal stent (LAMS). Stent displacement can be a serious complication, often requiring surgery.

We present the case of a 78-year-old man with GOO due to a metastatic adenocarcinoma of the duodenal bulb. Following obstruction of a previously placed duodenal metal stent, the patient was scheduled for an EUS-GE. With the patient under general anesthesia, a 20-mm dilation balloon (CRE; Boston Scientific) was passed over the wire through the stenosis into the jejunum under fluoroscopic guidance. Contrast medium with saline was injected through the balloon catheter to identify the target loop (► Fig. 1), which was then accessed with the electrocautery-enhanced delivery system of a 20-mm LAMS (AXIOS-EC; Boston Scientific) (► Video 1). A 0.035-inch guidewire was inserted through the LAMS delivery system to secure access to the jejunal loop, and the stent was released. On release, the distal flange dislodged from the jejunal loop into the peritoneum; however, the guidewire was still in place (► Fig. 2). Suction was applied to maintain apposition of the target loop with the stomach while a second 20-mm LAMS was successfully placed over the guidewire through the first LAMS (► Fig. 3). The LAMS-in-LAMS system was then dilated with a balloon up to 20 mm. Screening with contrast medium passed through the stents revealed no evidence of leakage.

If a wire access to the target loop is not preserved, LAMS misdeployment can require a natural orifice transluminal endoscopic surgery (NOTES)-based approach [4] or surgery. Wire access should therefore always be preserved to allow a minimally invasive rescue approach [5]. The

► **Fig. 1** Identification of the jejunal target loop on: **a** fluoroscopic view, showing a 20-mm dilation balloon passed through the duodenal stent (red arrows) and the target loop (*) with contrast medium inside it; **b** endoscopic ultrasound view, showing the target loop with liquid inside (*) in close apposition to the gastric wall (red arrows). The white arrow indicates the tip of the electrocautery-enhanced lumen-apposing metal stent delivery system.

► **Video 1** Video showing the lumen-apposing metal stent (LAMS)-in-LAMS rescue technique for salvaging a misdeployed LAMS during an endoscopic ultrasound-guided gastroenterostomy. The second LAMS (yellow dashed line) was released through the first misdeployed LAMS (red dashed line) on a preserved wire access to the target loop.

LAMS-in-LAMS technique is an effective procedure for salvaging a misdeployed LAMS during EUS-GE, assuring correct lumen apposition between the stomach and jejunum without need for any further device.
