Multiple granular cell tumor of the colon

A 44-year-old man was referred to our endoscopy unit because of a family history of colorectal neoplasia. Colonoscopy revealed numerous semi-pedunculated polyps with intact mucosa, measuring 6–12 mm, in the cecum ($n = 2$), ascending ($n = 5$), and transverse ($n = 2$) colon. The two largest polyps, measuring 8 mm and 12 mm, respectively, and occurring in the ascending colon (● Fig. 1), were removed by snare polypectomy. Histologic examination of the polyps revealed a submucosal tumor composed of cells with small round nuclei and abundant granular eosinophilic cytoplasm (● Fig. 2). Immunohistochemical analysis showed the tumor cells expressed S-100 protein (● Fig. 3). The resected polyps were diagnosed as granular cell tumor (GCT). Upper endoscopy, enteroscopy by videocapsule, and abdominal computed tomography scan were unremarkable. The patient entered an annual endoscopic follow-up program. GCT is a rare tumor that may occur in any site of the body [1,2]. It commonly occurs in the oral cavity, the skin, and the subcutaneous tissue, and is seldom found in the gastrointestinal tract [1,2]. In the gastrointestinal tract, the most common site is the esophagus, followed by the large intestine [1,2]. Gastrointestinal GCT is usually found incidentally during endoscopy as a submucosal tumor and is multiple in 10%–20% of all cases (15 patients described in the literature) [2]. The final diagnosis of GCT depends on pathologic findings: cells with small, uniform nuclei and abundant granular eosinophilic cytoplasm containing acidophilic, periodic acid-Schiff (PAS)-positive, diastase-resistant granules, and expression of S-100 protein or neuron-specific enolase [1,2]. GCT is usually clinically and histologically benign, with only a few malignant GCT cases reported [1,2]. Malignant behavior is suggested by large size (> 4 cm), rapid growth, and invasion of the adjacent tissues rather than the histologic features [1,2]. As gastrointestinal GCTs are considered benign, a conservative approach is suggested by means of endoscopic resection and a strict endoscopic follow-up [2].

Fig. 1 Narrow-band imaging showed three semi-pedunculated polyps covered by normal mucosa in the ascending colon.

Fig. 2 Histologic examination of the polypectomy specimen showed a submucosal tumor composed of cells with abundant granular cytoplasm. (Hematoxylin and eosin, $\times 50$).

Fig. 3 Immunohistochemical examination for S-100 protein revealed diffuse and strong expression of S-100 protein in tumor cells ($\times 50$).
