Abstract: An efficient three-step synthetic route to imidazole-fused benzodiazepines from imidazole-2-carbaldehyde is described. Application of intramolecular Buchwald–Hartwig cycloamination reaction in the final step is shown to be a convenient method for the synthesis of fused seven-membered diazacycles. The reactions proceeded smoothly with both aliphatic and aromatic amines.

Key words: palladium, catalysis, amination, cyclization, benzodiazepine

There is a growing interest over the past few years in the synthesis of nitrogen containing heterocycle-fused benzazepines and benzodiazepines due to their crucial role as main structural motif in many pharmacologically active molecules. The clinical importance and commercial success associated with the benzodiazepine class of central nervous system (CNS)-active agents and the utility of 1,4-diazepines as peptidomimetic scaffolds have led the medicinal chemists to recognize them as privileged structures. Particularly, imidazobenzodiazepines¹ and related ligands interact selectively for a neuro-inhibitory, post-synaptic GABA_A receptor^{1f,g} with high affinity. Accordingly, they may act as agonists, partial agonists,^{1b} and antagonists. The therapeutic applications of benzodiazepines include anxiolytics,² antiarrhythmics,³ vasopressin antagonists,⁴ and cholecystokinin antagonists.⁵ Some of the benzodiazepines such as arfendazam, lofendazam,⁶ triflubazam,⁷ and clobazam exhibit a wide range of biological activities while others like telenzepine act as anti-secretory agents.⁸ Recently, several compounds have been formally licensed for clinical use (e.g., Nevirapine) and others are at the preclinical and/or clinical development stage (e.g., Tivirapine and UK-129 485⁹). Tetrahydroimidazo[4,5,1-*jk*][1,4]benzodiazepin-2(1*H*)-thione, assigned the acronym TIBO,^{1d,e} is the first member of a series of potent selective and noncompetitive inhibitors of HIV-1 reverse transcriptase.

Despite the immense importance of imidazobenzodiazepines, only a few groups¹ have reported their synthesis. These methods either require lengthy sequence of reactions or harsh reaction conditions. For quite some time, we have been engaged in the synthesis of several benzanulated and dibenzannulated medium ring heterocycles

employing palladium-catalyzed intramolecular C–N bond forming cyclization reaction.^{10–12} The copper- or palladium-catalyzed intramolecular Buchwald–Hartwig aryl amination reaction¹³ appeared particularly suitable for this purpose. In continuation of these efforts, we became interested in applying this method in the synthesis of imidazole-fused benzodiazepines. To the best of our knowledge no other group has reported the synthesis of this important synthetic target using this method.

The requisite starting materials **3a–c** were prepared in good to excellent yields by reaction between imidazole-2-carbaldehyde (**1**) and either 2-bromobenzyl bromide (**2a**) or substituted 2-bromobenzyl bromides **2b,c** in the presence of anhydrous potassium carbonate in anhydrous DMF at room temperature (Table 1).

^a Reaction conditions: imidazole-2-carbaldehyde (1 equiv), 2-bromobenzyl bromide (1.2 equiv), K₂CO₃ (2 equiv), anhyd DMF (5 mL/mmol), r.t., 16–17 h.

^b Isolated yield.

Imine formation with aliphatic and aromatic amines and subsequent NaBH₄ reduction in ethanol afforded the desired amine precursors **4a–l** in good yields (Table 2).

The amine precursor **4a** was then used as model substrate for the optimization of intramolecular cycloamination reaction. Initially with the conditions used by Buchwald^{13a} (Table 3, entry 1) no desired product was obtained and the starting material **4a** was recovered. Changing the catalyst to Pd₂(dba)₃ or Pd(OAc)₂ also failed to afford the desired

^a Reaction conditions: 1) N-benzylated imidazole-2-carbaldehyde (1 equiv), amines (1.5 equiv), EtOH (10 mL/mmol), r.t., 12 h. 2) NaBH₄ (2.5 equiv), EtOH (20 mL/mmol), 0 °C, 2–3 h.

^b Isolated yield.

product in the absence of a ligand (entries 2, 3). The reaction did take place in the presence of a ligand, with Pd₂(dba)₃ proving superior to Pd(OAc)₂ at equivalent (10 mol% Pd) catalyst loading (entries 4–7), but the yield was still low (58%). Then, the Pd loading was varied from 6 to 40 mol% using Pd₂(dba)₃ as Pd source, which improved the yield to 73% at 20% Pd loading (entry 9). Changing the base to Cs₂CO₃, using other monodentate (tri-*o*-tolylphosphine) or bidentate (DPPF) ligands and employing different solvents (DME or 1,4-dioxane) proved less satisfactory (entries 12–16).

Use of copper catalyst (CuI, 5 mol%) and *t*-BuOK (2 equiv) with different ligands [1,10-phenanthroline or (±)-*trans*-1,2-cyclohexanediamine or *N,N*-dimethylethylenediamine, 10 mol%] and solvents like DMF (at 120 °C) or toluene (reflux) also did not lead to the desired cyclic product.

The optimized protocol for the palladium-catalyzed intramolecular aryl amination of **4a** thus employs Pd₂(dba)₃ (10 mol%) as catalyst, (±)-BINAP (10 mol%) as ligand,

^a Pd (10 mol%) refers to Pd₂(dba)₃ (5 mol%), Pd(OAc)₂ (10 mol%), and Pd(PPh₃)₄ (10 mol%).

^b Isolated yield.

^c No desired product was isolated.

^d Optimized reaction conditions: **4a** (1 equiv), Pd₂(dba)₃ (10 mol%; 20 mol% in Pd), (±)-BINAP (10 mol%), *t*-BuOK (2 equiv), toluene (10 mL/mmol), reflux.

t-BuOK (2 equiv) as base, and toluene as solvent at reflux to furnish **5a**. Employing these conditions, other substrates **4b–l** were treated to afford **5b–l** in 63–76% yield (Table 4). A probable mechanism^{13b,c,14} of intramolecular aryl amination for the synthesis of benzodiazepines is outlined in Scheme 1.

The assigned structures of **5b–l** were determined on the basis of their IR, ¹H NMR, ¹³C NMR, mass spectra, and elemental analysis. The ¹H NMR spectrum of **5a** consisted of two singlets at δ = 4.95 and 4.86 for the benzylic methylene protons and methylene protons attached to ni-

Scheme 1 Proposed mechanism for the synthesis of imidazobenzodiazepine

trogen of the aniline moiety, along with signals for eleven aromatic protons ($\delta = 6.77\text{--}7.42$). The ^{13}C NMR spectrum showed signals assignable to 17 carbons in agreement with the structure. The mass spectrum displayed a peak at m/z 262 for the $[\text{M} + \text{H}]^+$ ion. The features of the ^1H and ^{13}C NMR spectra of compounds **5b–I** were broadly similar to those of **5a**, except for the signals for the aromatic moieties and the alkyl/aryl groups, which exhibited the expected changes in signal patterns.

The present strategy thus establishes transition-metal-catalyzed cycloamination as a suitable synthetic tool for the preparation of imidazole-fused benzodiazepine. But it could not be extended to the synthesis of pyrrole-fused benzodiazepines.

In summary, we have established a straightforward efficient three-step synthetic route to imidazole-fused seven-membered diazacycles from imidazole-2-carbaldehyde using palladium-catalyzed intramolecular cycloamination reaction as the key step. Development of new analogues

of benzodiazepines is highly desirable as this may lead to a promising antidepressant drug. This finding opens up the possibility of obtaining synthetically challenging imidazole-fused seven-membered benzoheterocycles.

Reactions at r.t. imply a temperature of 25°C . Required reagents were obtained from commercial sources and used without purification. The solvents used were of technical grade, and freshly distilled prior to use. All melting points were obtained on a laboratory melting point bath and are uncorrected. ^1H (300 MHz, 600 MHz) and ^{13}C (75 MHz, 150 MHz) NMR spectra were recorded using CDCl_3 as solvent and TMS as internal standard on Bruker DPX 300 MHz and Bruker DRX 600 MHz NMR instruments. Chemical shifts are stated in parts per million in δ scales. IR spectra were recorded on a Jasco-FTIR Model-410 using KBr pellets or in neat condition. Mass spectra were measured in ESIMS (+) or EIMS mode. DI-EIMS were recorded on a Shimadzu GCMS (model no QP5050A) and ESIMS were done on a Waters Micromass Q-TOF microTM mass spectrometer. TLC was performed on precoated plates (0.25 mm, silica gel 60 F_{254}). Petroleum ether (PE) used refers to the fraction boiling in the $60\text{--}80^\circ\text{C}$ range.

^a Isolated yield.**1-(2-Bromobenzyl)-1H-imidazole-2-carbaldehydes 3a–c; General Procedure**

To a stirred solution of imidazole-2-carbaldehyde (**1**; 0.5 g, 5.2 mmol) in anhyd DMF (20 mL) was added K₂CO₃ (1.4 g, 10.41 mmol) and the mixture was stirred at r.t. for 30 min. Thereafter, the appropriate 2-bromobenzyl bromide **2** (6.25 mmol, 1.2 equiv) was added and the stirring was continued for about 16–17 h at r.t. On completion of the reaction as monitored by TLC (eluent: PE–EtOAc, 1:1), the solution was poured into H₂O (70 mL), and extracted with EtOAc (4 × 30 mL). The combined organic layers were washed with H₂O (40 mL), followed by brine (30 mL), dried (Na₂SO₄), filtered, and the solvent was evaporated in vacuo. The crude product was purified via column chromatography over neutral alumina (EtOAc–PE, 1:9) to give **3a–c**.

1-(2-Bromobenzyl)-1H-imidazole-2-carbaldehyde (3a)

Yield: 1.30 g (95%); yellow solid; mp 80–82 °C; *R*_f = 0.55 (PE–EtOAc, 3:2).

4,10-Dihydro-5H-imidazo[2,1-c][1,4]benzodiazepines 5a–l; General Procedure

To a stirred solution of **4a–l** (0.92–1.63 mmol, 1 equiv) in anhyd toluene (15 mL) were added *t*-BuOK (1.84–3.26 mmol, 2 equiv), ($\pm$)-BINAP (10 mol%), and $\text{Pd}_2(\text{dba})_3$ (10 mol%, Pd: 20 mol%). The reaction mixture was refluxed for 14–18 h under N_2 atmosphere. After completion of the reaction (monitored by TLC, eluent: EtOAc), toluene was evaporated under vacuum, and the mixture was extracted with EtOAc (3×20 mL). The combined organic layers were washed with H_2O (3×20 mL), followed by brine (30 mL), dried (Na_2SO_4), filtered, and the solvent was evaporated under vacuum. The crude mass was purified by column chromatography over neutral alumina to afford the desired compounds **5a–l**.

4,10-Dihydro-5H-phenylimidazo[2,1-c][1,4]benzodiazepine (5a)

Yield: 0.21 g (73%); brownish sticky mass; R_f = 0.51 (PE–EtOAc, 3:7).
