Direct Catalytic Asymmetric Synthesis of N-Heterocycles from Commodity Acid Chlorides by Employing α,β -Unsaturated Acylammonium Salts
Angew. Chem. Int. Ed. **2013**, DOI: 10.1002/anie.201306050.

Synthesis of Pyrrolidinones via α,β -Unsaturated Acylammonium Ions

Significance: An asymmetric enantioselective Michael addition–proton transfer–lactamization or lactonization organocascade reaction is reported. The cinchona alkaloid derived catalysts **1** can generate chiral α,β -unsaturated acylammonium salts with crotonyl chlorides **2**, giving pyrrolidinones, piperid-2-ones, and dihydropyridinones in good yields and high enantioselectivities.

Comment: In the first step, the lithiated enolate is formed to participate in a conjugate addition to the acylammonium species, which derives from reaction of the chiral tertiary amine ($R^3_3\text{N}$) with the acid chloride. After an intra- or intermolecular proton transfer, the acylammonium species undergoes intramolecular lactamization to regenerate the tertiary amine catalyst $R^3_3\text{N}$. The products could be transformed into known precursors of various biologically active compounds.
