WCC 2016-105: Risk Stratification of Women with Peripartum Cardiomyopathy at

Initial Presentation: A Dobutamine Stress Echocardiography Study

R V Venkata Rao, G Ramesh, D Seshagiri Rao, O Sai Satish, LSR Krishna, M Adithya.

Objectives: We sought to determine the prognostic use of inotropic contractile reserve on risk stratification and prognostication of women with peripartum cardiomyopathy.

Background: Peripartum cardiomyopathy is a rare disorder effecting women in their prime years of life. There appears to be an initial high-risk period with 25% to 50% of women dying within the first 3 months postpartum. Early risk stratification and prognostication are, thus, crucial. However, only limited data are available.

Methods: In all, 10 women (mean age 20.7 years) with peripartum cardiomyopathy and severe left ventricular (LV) dysfunction (mean LV ejection fraction [LVEF] $27.3 \pm 6.5\%$) were studied. Of these, 8 underwent dobutamine stress echocardiography at baseline and a follow-up resting echocardiogram at a mean of 3.6 ± 0.9 months after initial presentation. Resting and peak inotropic contractile reserve, and follow-up LVEF, were computed.

Results: The mean LVEF improved significantly from baseline ($27.3 \pm 6.5\%$) to maximal inotropic contractile reserve ($52.6 \pm 11.2\%$) ($P = .0004$) and at follow-up ($54.2 \pm 14.3\%$) ($P = .006$). Importantly, LVEF at maximal inotropic contractile reserve and at follow-up (3.6 months) did not differ significantly. The mean LVEF at maximal inotropic contractile reserve correlated well with the follow-up (LVEF $R = 0.79$). However, the baseline LVEF did not correlate with follow-up LVEF.

Conclusions: In patients presenting with peripartum cardiomyopathy, inotropic contractile reserve during dobutamine stress echocardiography accurately correlates with subsequent recovery of LV function and confers a benign prognosis.
