Leonardo Da Vinci said, “simplicity is the ultimate sophistication.”¹ This applies to solutions for any problem, including those of the medical profession. Unlike medical specialties, surgeons are confronted with the additional danger of the COVID-19 viral transmission intraoperatively. Reports suggest conjunctiva as one of the portals for entry of SARS-CoV-2, for which use of protective eye goggles is warranted.^{2–4} However, with the use of commonly available protection goggles, fogging while operating makes their use cumbersome (►Fig. 1).⁵ Even with the best available antifogging coated goggles, a thin layer of fluid forms on the inside, which deteriorate the vision, thereby putting the patient at risk (►Fig. 2). Surgeons and surgical staff around the world face this issue and often need to take off the goggles for cleaning during the procedure. This puts the surgeon at risk due to breach in protection. The commercially available solution to this is the powered air circulating headgear. But in addition to deteriorating the verbal communication between the operating team members, they are highly cost-restrictive, especially for the resource-constrained settings. The reason behind the formation of fog on the inside of the protective goggles is the accumulation of sweat vapors which condense on the cold glass. This happens due to the absence of ventilation inside. One understands that if sweat vapors can escape out from the inside of the goggles, it would prevent fog formation. This can be achieved by attaching a circuit for clean air/gas inflow/outflow in the existing protective goggles. We suggest the use of a nasal prong cannula, which is a readily available disposable in any operation theater (OT). After the surgeon is donned with the personal protective equipment (PPE) and scrubbed, an assistant places a nasal prong cannula above the glabella on the forehead pointing downward and secures it behind the head followed by placement of the

eye protection goggles over it (►Fig. 3). The next step is to arrange for the source of clean air or an inert/nonirritant gas for this circuit. Other than a commercially available powered air purifying respirator (PAPR) pump, there are other sources of clean airflow easily available in any OT. These include the compressed air points (medical or surgical) in OT pendants, central oxygen points, and even oxygen cylinders. Using a flowmeter, the flow of air/gas from any of these sources can be titrated and channeled to the inside of the goggle by attaching it to the nasal prong cannula worn by the surgeon. For the compressed air points, the routinely available oxygen flow meter will require modification of the connector accordingly. As the final step, regulated flow of air/oxygen is initiated and titrated at an effective and comfortable level. The small gaps created by the cannula tubing while entering on the inner side of the goggles shall allow air/gas to escape along with the sweat vapors. This will thereby limit fog formation (►Fig. 4). At the end of the procedure, the nasal prong tubing is discarded similar to the other disposable PPE items.

With the emergence of COVID-19 pandemic, health care specialties have witnessed significant changes in the practice patterns. As more knowledge is gained about the virology and pathobiology of SARS-CoV-2, guidelines emerged to curtail the transmission. Although the primary route of entry of SARS-CoV-2 is respiratory, further research has suggested other portals in the human body for entry of this virus. It was found that SARS-CoV-2 can be transmitted by ocular route via blood-mixed aerosols and particulate matter.^{2–4,6} Hence, eye goggles and safety face shields are mandatorily employed to protect eyes and curtail ocular transmission of SARS-CoV-2.⁴ SARS-CoV-2 induces inflammation and increases expression of angiotensin-converting enzyme 2 (ACE2) receptor and entry protease TMPRSS2 on the

Fig. 4 The airflow using the cannula is titrated to a comfortable level to limit fog formation while the surgeon is operating.

conjunctival, limbal, and corneal epithelium.² Quantitatively, these receptor proteins were found to be low in ocular surfaces, yet there are reports of detection of SARS-CoV-2 RNA particle in conjunctive and tear film.^{3,7} Many patients infected with SARS-CoV-2 have reported eye signs, especially follicular conjunctivitis as one of the presenting features.⁴ As the knowledge about SARS-CoV-2 pandemic is increasing, we will eventually know the precise transmission potential of this virus through ocular surfaces. But at this stage, it is wise to take every necessary protection measure, in order to prevent the transmission. It is, therefore, recommended to use protective eye goggles and face shield/visors to protect eyes.⁴ Often due to fogging in the spectacles and inner surface of these goggles, vision gets obscured.⁸ As a result, these become uncomfortable to wear and cannot be used continuously for a longer duration of time. This is a well-known concern for all surgeons who have to wear these eye protection goggles while operating. Antifog sprays are used to reduce fogging by virtue of their surfactant effect.⁹ But even with the use of the best available antifogging sprays or coatings, as condensation happens, a thin layer of fluid forms on the inner surface, which ultimately deteriorates the vision by chromatic aberration. The commercially available solution to prevent fogging is the powered air purifying respirators (PAPRs) with a headgear. But apart from being highly cost-restrictive, they also lead to significant deterioration in verbal communication between the team members in such critical areas.¹⁰ Proposed technique can facilitate the use of routinely available eye protection goggles without impairing the visibility, due to fog or condensation film, and reduce the frequent handling of eye goggles by keeping the surgeon comfortable for long hours without added cost. Using nasal prong cannula may meet opposition, because it is not a standalone eye-protective device, but an add-on to the protective eye goggles. Individuals may oppose using another device on top of unwieldy personal protective gear to prevent fogging.

Conflict of Interest

A.S. reports pending patent application at IPO. The remaining authors do not report any conflict of interest.
