Intravenous thrombolysis: Still an important tool in the management of severe ischemic stroke patients

Stroke continues to be the second leading cause of death worldwide. This mortality burden has come with more than a doubling of the stroke incidence in low- and middle-income countries, surpassing the incidence rates observed in most high-income countries. Stroke is also the leading cause of death and accounts for 1 in 7 deaths in a rural community in Gadchiroli, one of the most backward districts of India. There is high early mortality because of stroke and stroke is emerging as a public health priority in rural India.^[1]

In this issue of *Journal of Neurosciences in Rural Practice*, Dharmasaroja and Muengtaweepongsa^[2] describe the results of a retrospective case-control study comparing the outcomes of patients with acute moderate to severe ischemic strokes (The National Institutes of Health Stroke Scale [NIHSS] score of ≥ 15) with and without intravenous recombinant tissue plasminogen activator (rtPA) thrombolysis treatment. From January 2011 to May 2014, 240 patients with clinical deficits suggestive of anterior circulation large vessel occlusion and presentation to the Thammasat University Hospital within 24 h after symptom onset were included to the study. Computed tomography (CT) imaging was performed at admission and intravenous rtPA was initiated to 120 eligible patients within 4.5 h time window. In contrast, 120 patients were not treated with rtPA mainly due to CT demonstrated extensive early ischemic changes. Intravenous thrombolysis improved functional outcome at 90 days, with more patients achieving functional independence (39% vs. 17%). In addition, mortality was higher among patients who did not receive rtPA treatment (51% vs. 16%) and there was no sign of increased bleeding risk in the rtPA group (6% vs. 4%).

Unfavorable outcomes with up to 41% mortality rate at 3 months have been previously reported regarding the natural history of proximal intracranial arterial occlusions with a baseline NIHSS score of 10 or higher.^[3] In addition, despite intravenous thrombolysis within 3 h time window in patients with hyperacute internal carotid artery or proximal M1 segment of the middle cerebral artery (MCA) occlusion with a median NIHSS score of 18, there was a significant decrease in

functional independency (18% vs. 71%) and increase in mortality (32% vs. 3%) compared to a more distal occlusion with a median NIHSS score of 11.^[4] However, there is a greater benefit of intravenous thrombolysis compared to placebo in patients with increasingly severe strokes (NIHSS score of ≥ 15).^[5]

In most instances, nonenhanced CT will provide the necessary information to make decisions about the use of rtPA treatment in hyperacute ischemic stroke. A structured scoring system, such as the Alberta Stroke Program Early CT Score (ASPECTS) can quantify the extent of early ischemic changes in the MCA territory. In addition, the accuracy of the ASPECTS is markedly improved by the optimization of the window width and center level settings or by the use of CT angiography source images.^[6] An ASPECTS of ≤ 5 can be used as a guideline when evaluating $> 1/3$ of the region of territory involvement, a contraindication to intravenous thrombolysis.^[7] In contrast, if endovascular therapy for hyperacute ischemic stroke is considered, ASPECTS score of ≥ 6 is required, and a noninvasive intracranial vascular study is strongly recommended already during the initial imaging evaluation. However, for patients who qualify for intravenous rtPA, initiating intravenous rtPA before noninvasive vascular imaging is recommended for patients who have not had noninvasive vascular imaging as part of their initial imaging assessment for stroke. In addition, endovascular therapy with a stent retriever requires the patient to be at an experienced stroke center with rapid access to cerebral angiography, general anesthesia with intubation (if needed), and qualified neurointerventionalists within 6 h of symptom onset. The benefits of additional imaging such as CT perfusion, including measures of infarct core, collateral flow status, and penumbra, for selecting patients for acute reperfusion therapy, is still unknown.^[8]

The use of intravenous thrombolysis with rtPA for hyperacute anterior circulation ischemic stroke is associated with improved outcomes for a broad spectrum of patients, who can be treated within 3 h of symptom onset and for a more selective spectrum of patients who can be treated between 3 and 4.5 h after symptom onset. Ultimately, mortality and disability burden related to

hyperacute moderate to severe ischemic strokes can be safely decreased with management of eligible patients with intravenous rtPA when treatment is provided by acute stroke-ready hospital that has made an institutional commitment to evaluate, diagnose, and treat ischemic stroke patients effectively and efficiently.
