ABSTRACT

Acinetobacter baumannii is an important cause of nosocomial ventriculitis associated with external ventricular device (EVD). It is frequently multidrug resistant (MDR), carries a poor outcome, and is difficult to treat. We report a case of MDR *Acinetobacter* ventriculitis treated with intravenous and intraventricular colistin together with intravenous tigecycline. The patient developed nephrotoxicity and poor neurological outcome despite microbiological cure. Careful implementation of bundle of measures to minimize EVD-associated ventriculitis is valuable.

Key words: *Acinetobacter baumannii*, colistin, intraventricular, multidrug resistant, tigecycline, ventriculitis

Introduction

External ventricular device (EVD) is useful in monitoring intracranial pressure (ICP) in patients with severe traumatic brain injury and abnormal computed tomography (CT) scan of the head.^[1] However, the presence of EVD is a well-known risk factor for infection of central nervous system (CNS) with the incidence of 1–18%.^[2] *Acinetobacter baumannii* has emerged as an important nosocomial infectious agent due to its ability to tolerate desiccation and to accumulate diverse mechanisms of resistance.^[3] *Acinetobacter* meningitis is associated with high mortality ranging from 15% to 71%.^[4]

Successful treatment with intravenous and intrathecal/intraventricular colistin has been reported.^[2,3,5] There are few reports of successful use of tigecycline for

treatment of multidrug resistant (MDR) *A. baumannii* meningitis.^[6] Colistin is potentially nephrotoxic, which increases with higher cumulative dose and in patients with preexisting renal impairment.^[7] Here, we report a successful microbiological cure of EVD-associated MDR *Acinetobacter* ventriculitis using intravenous and intraventricular colistin together with intravenous tigecycline. However, the patient had progressive deterioration in neurological and renal function.

Case Report

A 75-year-old patient presented with the history of decreased level of consciousness and weakness in left half of the body following trivial fall. CT scan of the head revealed small right subdural hematoma with frontal contusion. Glasgow Coma Scale (GCS) was 7 (E₁V₁M₅) with bilateral equal and reacting pupils. Patient was planned for conservative management. He was intubated and put on mechanical ventilation for poor GCS. EVD

was placed for monitoring of ICP. Patient was on treatment with ceftriaxone 1 g 12 hourly for aspiration pneumonia. ICP was maintained at 10–15 mmHg.

After 3 days, patient had progressive drop in GCS to 4 (E₁M₃V₁). Repeat CT head revealed no new findings. EVD was in proper position and functioning. On the day 4, he developed high-grade fever (up to 103°F). EVD associated ventriculitis was suspected. Analysis of cerebrospinal fluid (CSF) sample revealed total count of 630 cells/mm³ with 90% polymorphs with sugar of 20 mg/dL and protein of 180 mg/dL. Corresponding blood sugar was 146 mg/dL. His serum creatinine level was 1.5 mg/dL. Antibiotics were empirically upgraded to vancomycin and ceftazidime. CSF sample was sent for culture and sensitivity which revealed *A. baumannii* sensitive only to colistin and tigecycline and resistant to all other antibiotics including carbapenems. Vancomycin and ceftazidime were stopped. Infected EVD was removed and a new ventricular drain was placed on opposite side.

Intravenous colistin was started at the dose of 2 million IU 8 hourly together with 200,000 IU through intraventricular route daily. Tigecycline was administered intravenously at a loading dose of 100 mg followed by 50 mg twice daily. CSF culture after 3 days of starting colistin and tigecycline was negative with decrease in cell count to 25 cells/mm³. Subsequent two consecutive CSF cultures done on alternate days were negative. The CSF analysis done on the day 7 of starting of colistin was normal. Patient was afebrile from the day 3. Intraventricular colistin was discontinued on the day 8. However, there was progressive decline in GCS to 2 (E₁M₁V₁). Serum creatinine level was followed daily. Due to progressive worsening of renal function, intravenous dose of colistin was decreased to 2 million IU 24 hourly on the day 5 when creatinine reached 4 mg/dL. Intravenous colistin and tigecycline was continued for 14 days when the family members of patient decided to withdraw the support due to anticipated poor neurological outcome despite microbiological cure of ventriculitis.

Discussion

Acinetobacter spp. possess an impressive armamentarium of resistance mechanisms rendering it resistant to almost all commercially available antibiotics.^[4] Colistin is widely used for the treatment of infections by MDR Gram-negative rods.^[8] However, intravenous administration of colistin is associated with a very low CNS transfer of only around 5%. A concomitant intraventricular administration

is required for treatment of severe ventriculitis in patients with EVD. The ideal dose, duration, and route of treatment are controversial.^[2] The literature review suggests a minimum intrathecal dose of 125,000 IU daily as suggested by the guidelines of Infectious Disease Society of America^[9] and may possibly increase to 250,000 IU daily. Intraventricular route was safe, effective, and well-tolerated.^[2] Hence, we administered 200,000 IU daily. Duration of intraventricular treatment <7 days is possibly associated with higher mortality.^[2] In our case, it was administered for 8 days. Combination of intraventricular and intravenous therapy was chosen as intraventricular therapy alone is not sufficient to treat EVD-related ventriculitis due to MDR Gram-negative pathogen.^[2]

Nephrotoxicity attributable to colistin therapy ranges between 0% and 53.5%. It is higher in patients with baseline renal dysfunction. Kidney injury is related to total cumulative dose and duration of therapy. As in our patient, older and more severely ill patients are at higher risk for nephrotoxicity, and it independently predicts higher mortality.^[7] Serum creatinine level was measured daily. Dose of colistin was adjusted with the renal function.

Tigecycline has demonstrated good *in vitro* activity against MDR *A. baumannii*, but current evidence does not support its use as monotherapy. Hence, tigecycline was used as a component of multidrug and multi-route therapy for our patient. Despite successful microbiological clearance, patient had poor neurological outcome. The bundle of measures such as education of Intensive Care Unit personnel, meticulous intraventricular catheter handling, and CSF sampling only when clinically necessary routine replacement of drainage catheter on the 7th day is associated with significantly decreased incidence of EVD-associated infection.^[10] It should be considered in all patients with EVD.

Conclusion

EVD-associated MDR *Acinetobacter* infection is associated with poor outcome. Intraventricular and intravenous colistin combined with intravenous tigecycline may be effective in microbiological clearance of bacteria. Bundle of measures should be implemented in all patients with EVD and at risk of MDR infection to prevent the disastrous outcomes.
