

Case Report

Temporalis Muscle cysticercosis: Common Parasite at Uncommon Location

Abstract

Isolated involvement of the temporalis muscle by cysticercosis is uncommon. The clinical features may mimic other inflammatory conditions of maxillofacial region or that of temporal headache. We describe here a case of right temporalis muscle cysticercosis that was initially misdiagnosed as dental caries. She clinically improved with albendazole and steroid. The radiology done after 6 months of therapy showed a complete resolution of the intramuscular lesion. Although rare, cysticercosis should be kept as one differential in patients present with unilateral temporal headache in endemic areas. Intramuscular cysticercosis can be diagnosed on the basis of radiological findings and respond well to pharmacological therapy.

Introduction

Cysticercosis involving the central nervous system is well known and most of them present with seizures. The involvement of skeletal muscles in the region of head and neck is less commonly reported in the literature.^[1] These cases are difficult to diagnose because of their rarity and the clinical features may mimic other maxillofacial pathologies. We here describe a case of isolated temporalis muscle cysticercosis in a young female, whose symptomatology mimics dental caries. Good clinical and radiological outcomes are noted after medical management. The differential diagnosis as well as the importance of radiological investigations in these rare entities further emphasized.

Case Report

A 28-year-old female presented to the outpatient neurosurgery department for evaluation of right temporal headache and difficulty in chewing for 3 months. She was diagnosed to have dental caries of the right second molar tooth at a local hospital and was initially considered the cause of her symptomatology. She was referred to us as she did not improve after 2 months of anti-inflammatory and analgesics. On evaluation, there was mild

tenderness in the right temporal region without any identifiable swelling. However, on palpation, there was induration over the right temporal area. There was no focal neurological deficit. Magnetic resonance imaging (MRI) was advised with a differential diagnosis of temporal arteritis. Radiology revealed a bulky right temporal muscle. There was an elliptical intramuscular enhancing lesion appeared hypointense on T1, hyperintense on T2 with eccentric hypointense dot and perilesional edema [Figure 1a and b]. A radiological diagnosis of temporalis muscle cysticercosis was made. Screening radiology of the brain was normal. She was advised albendazole 15 mg/kg body weight with a tapering dose of steroids (dexamethasone). She improved gradually and at 6-month follow-up, she was symptom free. MRI at the last follow-up showed complete resolution of the lesion [Figure 1c and d].

Discussion

Cysticercosis is endemic in Asian countries. Man acts as a definite host for the causative parasite *Taenia solium*.^[2] They spread to distant sites in the body through the bloodstream. Probably because of the high vascularity, these parasites have a strong predilection for the central nervous system. Most of the patients present with clinical

symptoms of seizure and headache. In the active phase, they respond well to antihelminthic drugs. At times when the parasite disseminates, it may affect the heart, lungs, eyes, and skeletal muscles.^[3] Very few cases of isolated temporalis muscle cysticercosis have been reported in the literature. Most often, such patients present with temporal headache with a palpable swelling, difficulty in chewing, and in acute inflammatory stage, they may also present with trismus.^[1] The accurate pathophysiology of isolated temporalis muscle cysticercosis is not known. Dissemination of the parasite through the bloodstream usually results in distant site cysticercosis. Theoretically, high flow through the internal carotid artery is responsible for high incidences of intracranial involvement. Accidental migration through the external carotid artery (ECA) may result in the deposition of the parasite at sites supplied by its terminal branches. Temporalis muscle receives extensive blood supply from the internal maxillary artery which is one of the terminal and large branches of ECA. This is probably the reason for temporalis muscle cysticercosis, an unusual extracranial site.

Due to their rarity, isolated skeletal muscle involvements are difficult to diagnose. Clinically, they mimic any

inflammatory pathology involving the maxillofacial region, as in our case. Cysticercosis may appear as a cystic lesion in the intramuscular plane with an echogenic nidus on ultrasound.^[3] On MR imaging, the T2 hyperintense lesion with hypointense focus (scolex) can be identified. Cysticercosis serology like enzyme-linked immunosorbent assay and enzyme-linked immunoelectrotransfer blot tests may further establish the diagnosis.^[4]

These cases usually manage with antihelminthic drugs. Albendazole 15 mg/kg body weight and praziquantel 50 mg/kg body weight per day in divided doses for 30 days is the standard treatment.^[3,4] Before starting drug therapy, screening of the brain should be done to look for associated neurocysticercosis and ocular cysticercosis where the latter considered as a contraindication for albendazole. Intramuscular cysticercosis usually responds well to medical management and may not require surgical interventions.

Conclusion

Isolated cysticercosis of the temporalis muscle, though rare, should be kept as a differential in patients from endemic areas presenting with unilateral pain and swelling of the temporal region. Careful evaluation of radiology is essential to establish the diagnosis. Good clinical and radiological improvement usually seen with drug therapy.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.
