Acute Generalized Chorea as Presenting Manifestation of Uremic Encephalopathy

Sir,

Renal dysfunction results in a clinical metabolic condition known as uremia. It causes altered mental status due to involvement of cerebral cortex termed as uremic encephalopathy. Acute hyperkinetic or hypokinetic extrapyramidal disorder in patients with uremia is a very rare syndrome. It was first described by Wang *et al.* due to bilateral basal ganglia lesions in uremia.^[1] Hereby, we report an elderly patient with diabetic nephropathy who presented with acute-onset generalized chorea. Brain magnetic resonance imaging (MRI) showed bilateral basal ganglia lesions. Choreiform movements got ameliorated with hemodialysis.

CASE REPORT

A 72-year-old male was brought to the emergency department with a history of disabling abnormal involuntary movements involving face and all limbs of 1-day duration. The movements were random, arrhythmic, continuous, nonstereotyped, partially suppressible that increased on activity. He had speech difficulty due to facial involuntary movements. There was no history of fever, altered mental status, seizures, myoclonus, diarrhea, or vomiting. He was diabetic and hypertensive of 7 years duration. He was diagnosed to have diabetic nephropathy for

1 year on medical management. On examination, his tongue was dry, pulse rate of 102/min, blood pressure of 146/86 mmHg, and respiratory rate of 20 breaths/min. Neurologically, he was conscious and responding to verbal commands with mild slurred speech. Fundus examination was normal. There was generalized choreiform movement involving face and all limbs. Asterixis could not be made out due to choreiform movements of limbs. Tone in limbs was decreased with sluggish reflexes. Plantar response was withdrawal. There was no neck rigidity. Complete hemogram showed raised total leukocyte counts (16,000 cells per cumm), normal platelet count, and hemoglobin. Serum electrolytes, random blood glucose, serum ammonia, and liver and thyroid function test were normal. Blood urea nitrogen was 76.4 mg/dl, creatinine of 6.2 mg/dl, and glycosylated hemoglobin of 8.2%. Blood gas analysis showed pH: 7.314, bicarbonate: 17.6 mmol/L, and lactate: 2.1 mmol/L. Brain MRI showed hypointense on T1 and hyperintense lesions on T2 and fluid-attenuated inversion recovery sequences in bilateral basal ganglia. Diffusion-weighted imaging showed no restriction in bilateral putamen [Figure 1]. Electroencephalogram showed mild slowing of background rhythm. He was started on sodium valproate (1 g/day) but had no improvement. He

Figure 1: Brain magnetic resonance imaging T1 coronal view (a) showed hypointense lesions (red arrow); T2 coronal (b), and axial (c) fluid-attenuated inversion recovery (d) showed hyperintense lesions in bilateral putamen (red arrow); diffusion-weighted (e) and apparent diffusion coefficient (f) showed no restriction (red arrow)

underwent hemodialysis with correction of metabolic acidosis. Choreiform movements gradually improved with concomitant decrease in creatinine level.

DISCUSSION

Uremic encephalopathy is an organic brain syndrome involving the cerebral cortex that is characterized by altered mental state ranging from mild confusion to comatose state, tremor, asterixis, multifocal myoclonus, and seizures.^[2] The involvement of basal ganglia is rare. Wang *et al.* reported a unique clinical condition in diabetic uremic patients characterized by acute movement disorder due to bilateral basal ganglia lesions. This was most commonly reported in Asian patients.^[3] The movement disorder can be either acute parkinsonism with patients presenting with rigidity, bradykinesia, and postural instability or chorea as in our case. There are two cases of generalized chorea due to uremia reported in Indian patients so far.^[4,5]

There are various explanations reported for the involvement of basal ganglia. Wang *et al.* performed F-18 fluorodeoxyglucose positron emission tomography on two diabetic uremic patients with bilateral basal ganglia lesions and demonstrated glucose hypometabolism in putamen, frontal, and occipital cortices. This may be due to compromised cellular function in basal ganglia due to diabetic microangiopathy or failure of utilization of energy compounded by the negative effects of uremic toxins and acid-base abnormalities on the basal ganglia cells.^[6] Basal ganglia lesions are due to cytotoxic edema surrounded by vasogenic edema (due to focal hyperemia secondary to abnormal dilatation of small vessels).^[7] Other explanations include hypoglycemia which may act as one of the trigger factors causing this syndrome as reported by Jurynczyk *et al.*^[8] Tajima *et al.* suggested that the basal ganglia lesions may be due to demyelination.^[9] There is difference in the resolution of clinical and radiological abnormalities. The resolution of clinical abnormalities may be complete in one-fifth of the cases, partial in half of the cases, and no resolution in 30% of the cases. However, resolution of the radiological abnormalities is observed in almost 90% of the cases.^[4] Our patient had complete clinical recovery within 1 week of initiation of hemodialysis.

Other causes of bilateral basal ganglia lesions include hypoxia, hyperammonemia, hypoglycemia, hyperglycemia, osmotic demyelination syndrome, deep vein thrombosis, toxins such as carbon monoxide poisoning, viral encephalitis such as Japanese

encephalitis, prionopathies such as Creutzfeldt-Jakob disease, and degenerative disease such as Wilson's disease.

CONCLUSION

Bilateral basal ganglia lesions in uremia are mainly due to the effects of metabolic abnormalities and uremic toxins on the compromised basal ganglionic cellular function causing cytotoxic and vasogenic edema. These abnormalities are potentially reversible if recognized promptly. This is the third reported Indian case of generalized chorea in uremia with bilateral basal ganglia lesions. The knowledge of this entity is necessary for the treating neurologists, nephrologists, and intensivists.
