Severe Extrapyramidal Syndrome Caused by Lurasidone Low Dose

Sir,
Second-generation antipsychotics (SGAs) are found to be safer in comparison to first-generation antipsychotics in producing extrapyramidal side effects. Lurasidone had shown good efficacy in schizophrenia as well as bipolar disorder.^[1,2] It has similar affinity for the dopamine D2 and serotonin 5-HT2A receptors

and a much greater affinity for 5-HT7, 5-HT1A, and α_2C -adrenergic subtype receptors than other atypical antipsychotics. As antagonism of 5-HT7 can improve cognition, memory, and mood symptoms, lurasidone is preferred in many clinical situations above other SGAs. The common side effects of lurasidone are nausea, vomiting, akathisia, dizziness, and sedation. Lurasidone

causing very severe extrapyramidal syndrome (EPS) is not so common.^[3,4] Here, we are presenting a case who presented with very severe EPS with intake of low dose of lurasidone.

Mrs. M, a 33-year-old married female living with her husband and four children, with well-adjusted premorbid personality and no significant personal and family history, presented with illness duration of 2 years which is insidious in onset and episodic in the course. On the background of interpersonal relationship issues with husband since marriage, she had first episode of illness with symptoms characterized by pervasive low mood, easy fatigability, anhedonia, social withdrawal, and reduced appetite. Following this, in the past 2 years, she had multiple similar episodes lasting for 1 month at a frequency of once in 5 months. The patient was started on escitalopram 4 months back. She showed good improvement in terms of the above-said symptoms. While on escitalopram, she presented with symptoms of reduced need for sleep, increased activity level, overcheerfulness, overspending, tall claims, and aggressive behavior. After this, escitalopram was stopped, then she was started on olanzapine, and eventually lithium was started with which she showed complete improvement in her symptoms, after which she was discharged. Within 1 month of discharge, she again showed depressive symptoms. Following this, olanzapine was stopped and quetiapine was started which she was not able to tolerate due to high sedation. Later, she was started on lurasidone 20 which was later hiked up to 80 mg. After 2 weeks of starting lurasidone, she came for follow-up reporting that she was not feeling comfortable with 80 mg of lurasidone and she was taking only 40 mg of it. On examination, she showed bilateral tremors, the rigidity of both upper and lower limb including the trunk, and stiff gait suggestive of extrapyramidal side effects. She scored 16 on Simpson–Angus Extrapyramidal side effect scale. Following this, lurasidone was stopped and lamotrigine was started. She was followed-up thrice over the next 3 months, during which no extrapyramidal signs were noted and she was maintaining well.

Lurasidone in low dose (40 mg) is not known to cause very severe EPS. Here, our patient developed generalized EPS scoring 16 in SAS. Need for adding anticholinergic increases when lurasidone is escalated from 40 mg to higher doses.^[3] Lurasidone has a potent affinity for dopamine D₂ and 5-HT_{2A} receptors; however, unlike most SGAs, it completely lacks binding affinity for histamine H₁ and muscarinic receptors. Probably, 5-HT_{1A} receptor activation attenuates EPS induced by dopamine D₂ blockade. Furthermore, lurasidone

has least cataleptogenic activities, of which the reasons are still unclear.^[1] However, our case showed significant disability due to severe EPS which aroused the possibility of other neurological disorders even though central nervous system examination was normal. Lurasidone is a well-suited drug for mood, anxiety, and psychotic symptoms with extra benefits of the least metabolic syndrome and high precognitive property. However, EPS produced with its low dose can reduce the efficacy and tolerability, leading to poor compliance. The case of lurasidone 40 mg causing such severe EPS with no earlier history of EPS with olanzapine and quetiapine is extremely rare. It could be due to high receptor affinity in a particular person and specific genetic variants.^[2,3]

Hence, we should be cautious even while writing comparatively safer and newer SGA and should not forget the propensity to develop EPS even in lower doses.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.
