Meckel’s diverticulum on third-generation video capsule endoscopy: intradiverticular ulcer, ectopic gastric mucosa, and active bleeding

A 29-year-old man presented with acute rectal bleeding causing hemorrhagic shock. The patient had presented with a similar episode of digestive bleeding 4 years previously, with no diagnosis being found. His physical examination did not reveal any clinical abnormalities. Gastroscopy, colonoscopy, and abdominal computed tomography angiography (CTA) were normal. Small-bowel video capsule endoscopy revealed an ileal diverticular orifice, with the double-lumen sign. After passage of the capsule into the diverticulum, an ulcer with a visible vessel (Forrest IIa) was observed at the bottom of the diverticulum, located next to a patch of heterotopic gastric mucosa. During this examination, active bleeding was seen from this area of ulceration (▶ Fig. 1; ▶ Video 1).

A Meckel’s diverticulum was suspected. A $^{99m}$Tc pertechnetate scintigraphy scan was performed, which confirmed the presence of ectopic gastric mucosa, corresponding to a probable Meckel’s diverticulum (▶ Fig. 2). Surgery allowed the excision of a diverticulum of $6 \times 2 \times 1$ cm that was found $70$ cm above the ileocecal valve. Histological examination confirmed the presence of ectopic fundal mucosa within the diverticulum (▶ Fig. 3). The patient left hospital 3 days after the surgery and has not represented with any further recurrence of bleeding.

Meckel’s diverticulum is a vestigial remnant of the omphalomesenteric duct, located on the antimesenteric border of the ileum, within $100$ cm above the Bauhin’s valve. About $50\%$ of symptomatic Meckel’s diverticula have been found to contain ectopic tissue, especially gastric mucosa ($35\%–45\%$), which can cause ulceration and hemorrhage; $75\%$ of hemorrhagic Meckel’s diverticula contain gastric ectopic mucosa [1]. Abdominal CT is an insensitive test for detection, especially in adults. In patients with obscure gastrointestinal bleeding, small-bowel video capsule endoscopy is a po-
Potentially interesting test for the diagnosis of Meckel’s diverticulum, with a positive predictive value up to 85% [2]. \(^{99m}\text{Tc}\) pertechnetate scintigraphy (Meckel’s scan), which specifically detects gastric mucosa, is more sensitive in a pediatric population (85%–90%) than in adult patients (60%). This test is particularly effective when there are symptoms related to the ectopic gastric mucosa, such as bleeding [3].
