Endoscopic treatment of complicated bile duct stricture after surgery for traumatic bile duct injury

Hepatic lesions are common in abdominal traumas [1] and generally involve liver parenchyma. Nevertheless, bile duct lesions are rare and challenging to treat [2, 3]. Biliodigestive anastomoses are the most frequently performed surgeries [3], but the risk of long-term adverse events is high, especially for biliary anastomotic strictures [4].

Here we present a case of traumatic biliary disconnection previously treated by biliodigestive latero-lateral anastomosis on Roux-en-Y-loop, complicated by anastomotic stricture. A 42-year-old man without relevant comorbidities was unseated from his horse and reported a severe bile leak due to intrapancreatic biliary tract disconnection. For this reason, he underwent hepaticojejunal latero-lateral anastomosis on Roux-en-Y-loop, with previous ligation of the distal choledocus. After six months, a biliary anastomotic stricture developed and percutaneous transhepatic biliary drainage was performed as the primary treatment. Because of the very low quality of life due to poor tolerance/compliance with percutaneous transhepatic biliary drainage, the patient was referred to our endoscopy center.

At first, a standard approach to the major duodenal papilla was attempted with a duodenoscope (ED-127; Pentax Medical), but it failed because the intrapancreatic biliary tract was completely disconnected. At this point, an occlusive cholangiography was performed (using a Fogarty balloon pushed into the bile duct through the percutaneous access) in order to make the common bile duct visible under endoscopic ultrasound. The Hot AXIOS electrocautery-enhanced delivery system (Boston Scientific) was chosen to change the approach, and a fully covered, 8 × 8-mm lumen-apposing metal stent (LAMS) was released between the duodenum and the choledocal stump.

Then a fully covered, 16-mm × 2-cm biflanged metal stent (Nagi Stent; EuroMedical Corp.) was placed through the hepaticojejunostomy using the percutaneous access to achieve stable dilation of the anastomotic stricture.

"Hand-tailored," fully covered, self-expandable metal stents placed through the choledochoduodenostomy crosswise to avoid excessive tension of the anastomotic area.

Occlusive percutaneous cholangiography using a 12-mm Fogarty balloon to dilate the common bile duct and make it visible under endoscopic ultrasound.

To safely open the lumen-apposing metal stent in a small-caliber common bile duct, the stent was placed as deep as possible in the biliary tract through a guidewire.

“Hand-tailored,” fully covered, self-expandable metal stents placed through the choledochoduodenostomy crosswise to avoid excessive tension of the anastomotic area.

Biflanged stent and lumen-apposing metal stent at 1-month follow-up.

Transhepatic biliary drainage was performed as the primary treatment.
At the six-month follow-up, both stents were removed, and two “hand-tailored,” fully covered, 6-mm × 3-cm self-expandable metal stents (WallFlex; Boston Scientific) were placed through the new choledocoduodenostomy to consolidate the anastomosis (▶Video 1). The stents were positioned crosswise in order to avoid excessive tightening on the walls of the biliary ducts (▶Fig. 4). These stents were removed after six months and, at the cholangiography, the choledocoduodenostomy was patent (▶Fig. 5). The patient remained asymptomatic and no recurrence of symptoms was reported.
