Thromb Haemost 2021;121:547–551.

Venous thromboembolism (VTE) is a common complication in patients with cancer and is associated with significant morbimortality and adverse outcomes.¹ Management of cancer-associated thrombosis poses challenges for clinicians. Compared with other patients with VTE, patients with cancer-associated VTE who receive anticoagulant therapy have a higher risk both for recurrent VTE and for bleeding complications.² Until recently, subcutaneous low-molecular-weight heparin (LMWH) monotherapy has been the standard of treatment for cancer-associated thrombosis.^{3–5} Compared with vitamin K antagonists, LMWHs may lead to reduction in VTE events though not in bleeding or mortality.⁶

Direct oral anticoagulants (DOACs) have become the anticoagulant treatment of choice for the majority of patients with acute VTE.³ Compared with vitamin K antagonists, in most subgroups, they are similar in efficacy but are associated with lower risk of major bleeding.⁷ In addition, these drugs are given in fixed doses and do not require laboratory monitoring of the anticoagulant effect. Several trials have assessed the efficacy and safety of DOACs for patients with cancer-associated thrombosis.^{8–11} A recent meta-analysis included four randomized trials (2,907 patients with cancer-related VTE) that compared apixaban (two trials), edoxaban (one trial), or rivaroxaban (one trial) with dalteparin.¹² Risk for recurrent VTE was 3.5% absolute points lower in patients treated with a DOAC, but clinically relevant nonmajor bleeding (CRNMB) was 4.7% higher. Though the risk of major bleeding was nonsignificantly higher, DOACs had a 6.6% significant absolute increase in the subgroup who had gastrointestinal cancer.¹² Broadly similar observations have been noted in other meta-analyses

of the DOACs for the treatment of acute VTE associated with cancer.¹³

The study by Ageno et al in this issue of *Thrombosis and Haemostasis* is a welcome addition to the body of evidence.¹⁴ Using data from the multicenter, randomized, open-label, noninferiority Caravaggio trial,¹¹ the authors investigated sites of bleeding, clinical presentation, and course of major bleeding. Among 576 patients randomized to apixaban, major bleeding occurred in 22 (3.8%) patients, compared with 23 of 579 (4.0%) patients randomized to dalteparin. The sites of major bleeding were similar between the two treatment groups. The clinical presentation of major bleeding was severe or fatal in 6 patients on apixaban and in 5 patients on dalteparin, while the clinical course was severe in 5 patients on apixaban and in 7 patients on dalteparin. Major bleeding occurred in 9 patients with gastrointestinal cancer in each treatment group. Finally, there were 52 CRNMBs in the apixaban group and 35 in the dalteparin group. Strengths of the study include high-quality data and thorough reporting. Study limitations comprise lack of competing risk assessment, and a low number of bleeding events that precludes further phenotyping, if a true difference were to exist.

The results reported by Ageno et al come from the largest trial to date evaluating the efficacy and safety of a DOAC for patients with cancer-associated thrombosis and suggest that treatment with apixaban might be associated with a better safety profile than other DOACs. In the Hokusai VTE Cancer Trial, major bleeding occurred in 36 patients (6.9%) in the edoxaban group and in 21 patients (4.0%) in the dalteparin group (hazard ratio [HR], 1.77; 95% confidence interval [CI], 1.03–3.04)⁸ (→ **Table 1**). There was also more CRNMB in patients receiving edoxaban

^aMedian values.

(HR, 1.38; 95% CI, 0.98–1.94). In a subgroup analysis of patients with gastrointestinal cancer, major bleeding rates favored dalteparin therapy (edoxaban 13.2% vs. dalteparin 2.4%; *p* = 0.02). Bleeding rates were similar in the patients with nongastrointestinal cancer. There were no fatal bleeding events in the edoxaban arm and one fatal bleed in the dalteparin arm. In the SELECT-D trial, major bleeding rates were 6% for rivaroxaban and 4% for dalteparin (HR, 1.83; 95% CI, 0.68–4.96).⁹ Most major bleeding events involved the gastrointestinal tract. Patients with upper gastrointestinal cancer were more likely to experience a major bleed with rivaroxaban compared with dalteparin. CRNMB was also more frequent with rivaroxaban (13% vs. 4%; HR, 3.76; 95% CI, 1.63–8.69) and primarily involved gastrointestinal or genitourinary sources.

The potential explanations for the differences in the risks of major bleeding events remain debatable, including the

differences in patient characteristics, protocol designs, distinct prespecified bleeding definitions, the anticoagulant dose or frequency (once vs. twice daily dosing), or other factors (►Table 1). The baseline characteristics of the patients randomized in Caravaggio were comparable with those of the previous studies.^{8,9} There were similar percentages of enrolled patients with gastrointestinal cancers as well as with active and metastatic cancers in these trials. The proportion of patients who were receiving anticancer treatment or had moderate renal insufficiency were also comparable. However, the presence of active luminal tumors (i.e., luminal gastrointestinal or genitourinary tumors) was not reported in either study. In addition, there were minor differences in the definition of major bleeding across these four trials (►Table 1). Nevertheless, similar rates of major bleeding event rates in the dalteparin arm of these trials

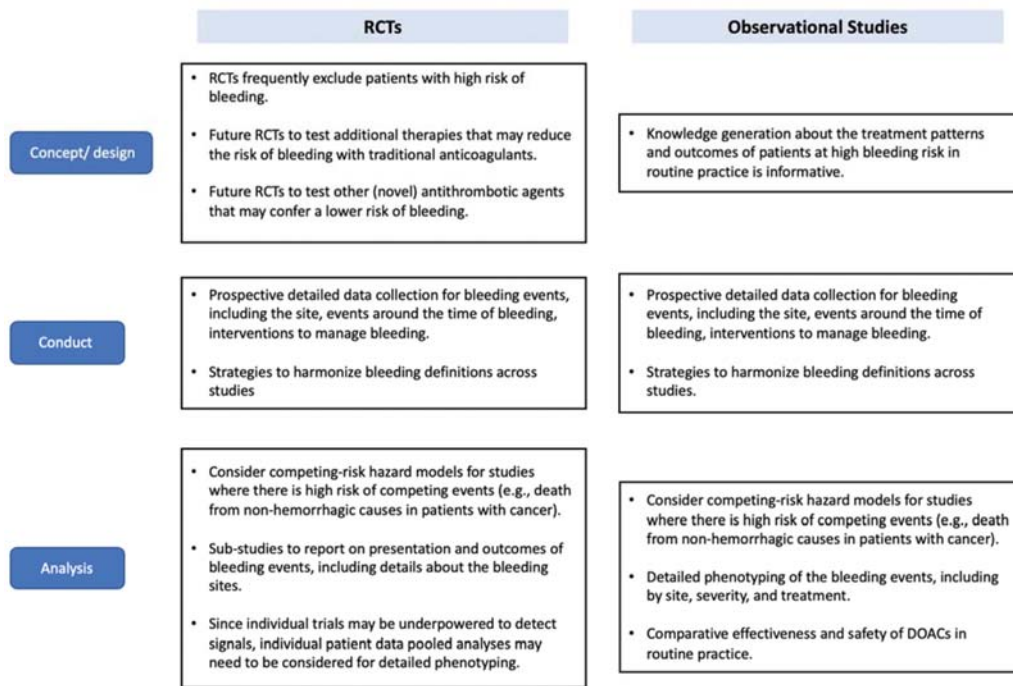

Fig. 1 Considerations for improved knowledge generation for bleeding events in patients receiving anticoagulant therapy. DOACs, direct oral anticoagulants; RCTs, randomized controlled trials.

make it unlikely that a large difference in case mix existed between them. Importantly, dabigatran, has not been specifically studied in this subgroup of patients.

What do we learn from this study for our clinical practice? DOACs provide an attractive alternative to LMWH in the treatment of VTE in cancer patients.¹⁵ At present, due to conflicting data, the use of DOAC for patients with gastrointestinal or urological malignancies would appear risky. If they have to be used for these patients, indirect comparisons suggest that apixaban might be the safest of the DOAC medications. Since it is unlikely that different DOACs will be compared in randomized controlled trials in near future, evidence derived from routine practice can provide key insights regarding how each anticoagulant is used under routine care conditions in diverse patient populations (► **Fig. 1**). For that purpose, data from large registries will complement the perspective from randomized studies.^{16–18}
