A 12-year-old boy was admitted to our hospital with sharp upper abdominal pain for the previous 5 days. Physical examination revealed epigastric tenderness but no rebound pain. The boy revealed that, 1 year previously, he had swallowed some sharp metal and magnetic objects, without ever telling either his parents or anyone else.

After his admission, a computed tomography (CT) scan was performed, which showed multiple masses and long strips of high density shadow on the greater curvature of the stomach, some of which appeared to be outside the gastric cavity (Fig. 1). Gastroscopy showed two clumpy foreign bodies (approximately 6 x 4 cm in size) in the gastric cavity, with many long foreign body strips attached, and that the stomach wall was swollen and eroded (Fig. 2a). A total of 19 iron nails and eight magnets shaped like rugby balls were removed using a pair of foreign body forceps during the endoscopy (Fig. 2b). However, when a repeat CT scan was performed on the second day after surgery, it was found that there was still an iron nail of approximately 5 cm in length in the child’s abdominal cavity (Fig. 3). This iron nail had passed through the gastric wall and fallen into the abdominal cavity, where it was assumed to have remained between the posterior wall of the stomach and the pancreas for approximately 1 year.

After multidisciplinary consultations with pediatric medicine, pediatric surgery, gastrointestinal surgery, gastroenterology, and other disciplines, we decided to remove the foreign body using natural orifice transluminal endoscopic surgery (NOTES). NOTES is an evolving minimally invasive surgery that aims to eliminate abdominal trauma and its related complications [1]. Compared with traditional surgery and laparoscopy, it has many advantages, including no scarring, less trauma, less pain, and a shorter surgical path [2, 3].

The patient’s parents signed an informed consent form for NOTES and the surgery was performed with the boy under endotracheal intubation and anesthesia. The procedure was performed in the following steps (Fig. 4; Video 1). (i) The locations of the foreign body and the gastric wall were detected using endoscopic ultrasonography (EUS) and an incision was made in the greater curvature of the middle part of the gastric body near the posterior wall. The entire layer of the gastric wall was incised using a DualKnife and IT-knife. (ii) The endoscope was passed into the small abdominal cavity, where extensive adhesions and wrappings were found between the posterior gastric wall and the pancreas;
however, no foreign body could be seen. (iii) The adhesions were separated and incised with the DualKnife and IT-knife. (iv) The foreign body was located using EUS, which showed that one end of it had become partially inserted into the pancreas. It was completely separated and loosened, and was then removed using foreign body forceps through the incision in the gastric wall. It was found to be a 4.8-cm iron nail. (v) The wound was treated with hot coagulation forceps, and the abdominal cavity was washed with metronidazole; the incision in the gastric wall was then sutured with endoclips and nylon loops.

The surgery was completely successful, and the patient had no abdominal pain, fever, or other discomfort after the operation. He recovered and was discharged on the fifth day after surgery.
