Direct large flow of venous gas into right atrium and ventricle during endoscopic biliary treatment

The patient, a 32-year-old woman, had undergone partial resection of the left lobe of the liver and extrahepatic bile duct with choledochojjunostomy for numerous intrahepatic biliary stones due to primary sclerosing cholangitis (Fig. 1). An afferent loop of jejunum–cutaneous fistula had also been surgically created for additional endoscopic treatment. Three months after surgery, we attempted endoscopic removal of the remaining stones using the jejunocutaneous fistula. An endoscope was inserted through the fistula to reach the biliary–jejunal fistula (Fig. 2). Choledochography showed multiple biliary strictures (Fig. 3). Several strictures were dilated with 1-mm to 8-mm balloons inflated using carbon dioxide (Fig. 4). When the balloon dilator was deflated and removed, fluoroscopy showed gas entering the right ventricle. No abnormal bleeding occurred from the bile duct. The endoscope was immediately removed from the jejunal–cutaneous fistula. Fluoroscopic investigation revealed no continuous leakage of gas into the ventricle (Video 1). Fortunately, computed tomography showed no sign of gas embolism in the various organs.

Fig. 1 Many intrahepatic stones were removed during surgery, but numerous stones remained.

Fig. 2 Biliary–jejunal fistula was stenotic.

Fig. 3 Endoscopic choledochography showed multiple biliary strictures with small stones.

Video 1 During an attempt at endoscopic removal of stones from a stenotic intrahepatic bile duct, the duct was sought using a guidewire. Several strictures were dilated, but when the balloon dilator was deflated and removed, fluoroscopy showed gas entering the right ventricle.
In this case, we speculate that, during the search using the guidewire, the guidewire had broken through from the bile duct into the hepatic vein. A large amount of gas then flowed into the bile duct from the intestinal tract and leaked into the hepatic vein because of dilation between the intrahepatic bile duct and intrahepatic vein. When a large amount of air enters the right atrium and ventricle, it is known to move to the left atrium and ventricle without being absorbed in the lungs, leading to air embolism in the brain [1]. It was fortunate in this case that carbon dioxide was used for the gas supply [2]. Awareness of the possibility of the event presented in this video may help clinicians to spot its occurrence early and manage the situation before it deteriorates further.

Endoscopy E-Videos is an open access online section, reporting on interesting cases and new techniques in gastroenterological endoscopy. All papers include a high quality video and all contributions are freely accessible online. Processing charges apply (currently EUR 375), discounts and waivers acc. to HINARI are available.

This section has its own submission website at https://mc.manuscriptcentral.com/e-videos
