Mucosal defect closure after gastric endoscopic submucosal dissection (ESD) is challenging because of the thick mucosal and muscle layers [1]; it is particularly difficult in the gastric antrum. When a conventional endoscope is pushed distally to access the antrum, the greater curvature is stretched. This widens the mucosal defect and stretches the muscle layer, making closure of the defect difficult (▶ Fig. 1). Herein, we present a multibending scope technique that allows antral defect closure using the reopenable clip-over-the-line method (ROLM) to avoid stretching the muscle layer [2].

A 60-mm mucosal defect was left after gastric ESD in our patient (▶ Fig. 2; ▶ Video 1). A multibending scope (GIF-2TQ260M; Olympus) was used with the second (top) wheel adjusted to a slightly upward position. Consequently, it was possible to confirm the anal side of the defect edge endoscopically, without stretching the muscle layer. Defect closure was performed using the ROLM, a defect closure technique using a line and reopenable clip (SureClip 8 mm, 16 mm; MicroTech, Nanjing, China) [3]. First, a clip with a line secured to the tooth was placed at the anal edge of the defect through the working channel. The line was passed through a hole in the tooth of the next reopenable clip, before it was also introduced into the working channel. This clip was placed on the contralateral defect edge and nearby muscle layer, with the line tightened over the closed clip before it was deployed. The same steps were repeated to gradually close the defect. Two ROLMs were required for complete defect closure in this case, and the remaining line was cut with a new loop cutter (FS-5L-1; Olympus) [4]. The patient was discharged, without experiencing any adverse events.

In conclusion, a multibending scope is effective for closing antral mucosal defects because it prevents stretching of the gastric muscle layer.
