Mucosal perforations, reported in 4.2%–17.3% of cases [1], are one of the major inadvertent complications of peroral endoscopic myotomy. Mostly, mucosal perforations occur at the gastroesophageal junction (GEJ), where the muscularis propria and mucosal layers are in close proximity, representing major challenges for endoscopic management [2]. This is largely related to the constrained position of the endoscope and the challenge of controlling the direction of the endoclips, particularly when using the retroflexed view below the cardia. Over-the-scope clips [3], endosutures [4], fibrin sealant [1], and even diluted cyanoacrylate [5] have been reported as being used in such situations, yet they are not usually available and their costs are high. Here, we demonstrate two successful cases using a unique and simple method for the closure of mucosal perforations using standard endoclips (▶Video 1). We used the previously created submucosal tunnel to provide a convenient space for easier application of endoclips, with better malleability and fewer numbers needed. Moreover, this was applicable both before and after endoscopic myotomy.

Both patients had a prior history of either Heller’s myotomy or endoscopic dilation, leaving extensive fibrosis at the GEJ, which resulted in difficult dissection and inadvertent mucosal perforation. In the first patient, the endoclip was applied after selective myotomy had been performed, because of the fear of further limiting the dissection space (▶Fig. 1). In the other patient, the endoclip was applied before myotomy (our recommendation), with the aim of avoiding any further unintended extension of the mucosal perforation during myotomy (▶Fig. 2). Both patients had uneventful follow-ups, with significant clinical improvement. Follow-up endoscopies revealed complete healing of the mucosal perforation.
in patient #1 (▶Fig.3); however, in patient #2, alongside complete healing, the endoclip was found hanging at the GEJ (▶Fig.4), which might be attributed to progressive narrowing of the healing intratunnel space. The endoclip was easily removed, without any adverse events.

To the best of our knowledge, this is the first report of this intratunnel technique, which seems to be feasible, easier, and less costly than the other previously mentioned modalities and with comparable safety. Evaluation of the long-term outcomes needs further large-scale studies.
