Endoscopic intermuscular dissection of a residual rectal neuroendocrine tumor with high-pressure injection and double-clip traction

Endoscopic resection, with advanced techniques such as modified endoscopic mucosal resection (EMR) or endoscopic submucosal dissection (ESD), is the first-line treatment for small grade 1 rectal neuroendocrine tumors (NETs), and complete histological resection is mandatory to avoid overtreatment or unnecessary follow-up [1]. Rectal NETs are rare tumors that can be misdiagnosed and consequently inadequately resected with cold snare, hot snare polypectomy, or biopsy forceps, leading to incomplete resection [2]. In such cases, complementary resection using ESD or transanal endoscopic microsurgery can be proposed to achieve complete resection and dispense with further follow-up [3]. Recently, endoscopic intermuscular dissection has been described to increase the deep resection margin for invasive submucosal rectal cancer [4].

We report the case of a 26-year-old man with previously incomplete resection by conventional EMR of a grade 1 10-mm rectal NET with deep margin involvement (Fig. 1). In order to achieve complete en bloc resection of the residual lesion with tumor-free margins, we performed intermuscular endoscopic dissection (Video 1). After marking the lesion, submucosal injection of glycerol mixed with indigo carmine and mucosal incision using a HybridKnife type I (Erbe Elektromedizin GmbH, Tübingen, Germany) were performed, followed by trimming of the submucosal layer. Then, a circumferential incision of the circular muscular layer was performed, with exposure of the longitudinal muscular layer (Fig. 2). Exposure of the intermuscular plan was improved with double-clip countertraction, with the clip grasping the internal circular muscular layer (Fig. 3). In addition, high-pressure glycerol injection through the HybridKnife was useful in dramatical...
ly enlarging the visible plan between the two muscular layers (Fig. 4) and performing safe complete endoscopic resection without damage to the longitudinal muscular layer. Histopathological examination of the specimen showed millimetric residual grade 1 well-differentiated NET, with lateral and deep free margins of more than 2 mm. The patient was discharged the same day and no adverse events occurred.

Endoscopic intermuscular dissection with traction and efficacious injection allows accurate resection of small rectal NETs, thus avoiding the risk of positive deep margins, and should be considered in order to protect against incomplete resection.

ENDOSCOPY E-VIDEOS
https://eref.thieme.de/e-videos

E-Videos is an open access online section of the journal Endoscopy, reporting on interesting cases and new techniques in gastroenterological endoscopy. All papers include a high-quality video and are published with a Creative Commons CC-BY license. Endoscopy E-Videos qualify for HINARI discounts and waivers and eligibility is automatically checked during the submission process. We grant 100% waivers to articles whose corresponding authors are based in Group A countries and 50% waivers to those who are based in Group B countries as classified by Research4Life (see: https://www.research4life.org/access/eligibility).

This section has its own submission website at https://mc.manuscriptcentral.com/e-videos
