Duodenal and rectal varices as a source of severe upper and lower gastrointestinal bleeding

A 57-year old patient was admitted with hematochezia and hematemesis. The patient’s history included portal vein cavernous transformation after posttraumatic splenectomy 34 years ago.

A nonbleeding elevated lesion with a small ulcer was detected in the descending duodenum, within a large convolute of varices (Fig. 1). Sigmoidoscopy on the following day revealed nonbleeding rectal varices. Duplex ultrasonography confirmed portal vein cavernous transformation. Given both upper and lower gastrointestinal collateral and bleeding, portosystemic decompression was considered. However, magnetic resonance imaging (MRI) angiography could not identify a patent vein adequate for a transjugular intrahepatic portosystemic stent shunt (TIPSS) or surgical shunting. Therefore, the patient was scheduled for endoscopic therapy.

During upper endoscopy, a massive amount of blood began to spurt from the previously identified ulcerated area on the varix (Fig. 2, Video 1). The bleeding was stopped by band ligation (Fig. 3). Band ligation of the rectal varices was carried out using a gastroscope in retroflexion. The patient was stable after successful ligation, and propranolol and a proton pump inhibitor were started. Follow-up endoscopy showed scarring after band ligation without stigmata of re-bleeding (Fig. 4). Four months after band ligation, scar formation was observed. Residual varices were again band ligated.

During band ligation, spurting bleeding from a large varix, which after band ligation without stigmata of re-bleeding (Fig. 4). Four months after band ligation, scar formation was observed. Residual varices were again band ligated.

The clinician often occurs from erosions on the varix, as in our patient, and has unanimously been reported as severe. The red colour sign seen in oesophageal varices is usually absent [4]. Because of the infrequency of ectopic variceal bleeding, treatment modalities have not been validated prospectively. This case report shows that bleeding from ectopic varices of the upper and lower gastrointestinal tract can be successfully treated by endoscopic band ligation.
