Gossypiboma successfully removed by endoscopy after endoscopic ultrasound-guided transmural drainage

Endoscopy is an emerging diagnostic as well as treatment modality for gossypiboma [1–5]. Here we report successful endoscopic removal of a gossypiboma after endoscopic ultrasound (EUS)-guided transmural drainage.

A 77-year-old man presented with abdominal pain. He had undergone an operation 30 years ago for alcohol-induced esophageal varices. Ultrasound (US) showed a well-delineated cystic mass containing internal high-echoic irregular mass-like debris (Fig. 1a). Abdominal computed tomography (CT) revealed a well-defined, 12-cm cystic mass, with internal whorled appearance and wall calcification, in contact with the pancreas and stomach (Fig. 1b), which was diagnosed as a pancreatic pseudocyst. We chose to puncture the cystic mass transgastrically with a 19-G needle (Echo-tip Ultra; Cook Medical, Bloomington, Indiana, USA) under EUS guidance, following which we inserted two 7-Fr double pigtail-type plastic stents (Olympus Medical Systems, Tokyo, Japan). About 1 month later, the diameter of the cyst decreased from 12 cm to 5 cm and it showed an altered spongiform internal appearance with scattered gas bubbles on CT (Fig. 1c). We considered the possibility of a gossypiboma, and an upper gastrointestinal endoscopy revealed surgical gauze protruding from the side of the plastic stents (Fig. 2a). We carried out balloon dilation (Hurricane RX, 10 mm wide dilation, 4 cm length; Boston Scientific, Natick, Massachusetts, USA) of the fistula (Fig. 2b) and using biopsy forceps, the gauze was fully extracted slowly without any complications (Fig. 2c and Video 1).

To our knowledge, this is the first reported case of a gossypiboma managed with endoscopy after EUS-guided transmural drainage. The gauze did not migrate into the lumen in our patient, but a pseudocyst was formed in response to long-term inflammation. After EUS-guided cyst drainage, the gauze protruded from the side of the inserted plastic stents, and we were able to remove it by transgastric endoscopy. We believe that this method may become a common treatment for gossypiboma in patients in whom the material has not migrated.
