Acute pancreatitis induced by vegetable fibers is a rare entity [1–5]. We report an unusual case of acute pancreatitis caused by a foreign body which had migrated into the main pancreatic duct. A 38-year-old woman was referred to our unit with recurrent acute pancreatitis. Serum amylase (286 U/L) and lipase (721 U/L) were elevated, and she complained of severe abdominal pain radiating to her back. The patient denied recent use of alcohol or drugs and also denied previous pancreatic or hepato-biliary disease, and surgical operations. Abdominal ultrason sound and contrast-enhanced computed tomography (CT) showed a dilation of both the common bile duct and pancreatic duct. Magnetic resonance cholangiopancreatography (MRCP) showed a 3-mm calcification in the pancreatic duct; the duct was slightly dilated. Endoscopic ultrasound (EUS) identified a 6-cm hyperechoic “tubular structure” in the pancreatic duct, with multiple irregular spots and a leaf-like ending, perfectly fitting the duct, up to the pancreatic isthmus. The “tubular structure” was removed endoscopically using a biopsy forceps (Fig. 3). Macroscopic examination showed that the foreign body was in fact a vegetable ear (Fig. 4). The patient was discharged after 2 days following rapid normalization of serum pancreatic enzymes. At 3-month follow-up, the patient was totally asymptomatic. In this case, EUS proved to be a valuable tool in detecting a pancreatic foreign body, while other imaging techniques (abdominal ultrasound, CT, MRCP) were inconclusive or misleading.
