Abstract  A robust method for preparing (E)- and (Z)-stereodefined fully substituted enol tosylates is described. α-Substituted β-keto esters undergo (E)-selective enol tosylations using TsCl–Me₂N(CH₂)₆NMe₂ as the reagent (method A, 13 examples; 63–96%) and (Z)-selective enol tosylations using TsCl–TMEDA–LiCl as the reagent (method B, 13 examples; 62–99%). A plausible mechanism for the (E)- and (Z)-enol tosylations is proposed. A ¹H NMR monitoring experiment revealed that TsCl coupled with TMEDA formed a simple N-sulfonylammonium intermediate.

Key words  stereocomplementary, stereodefined olefin, enol tosylate, tosyl chloride, TMEDA, diamine, NMR monitoring

Acyclic (E)- and (Z)-enol sulfonates (tosylates, triflates, etc.) and phosphonates derived from readily accessible β-keto esters are well-recognized synthetic precursors of stereodefined olefins produced using stereoretentive cross-coupling methodology.¹ A number of biologically active compounds and functionally useful materials comprise these acyclic stereodefined olefins. Among several enol sulfonates, (E)- and (Z)-enol tosylates are particularly advantageous due to their stability, cost-effectiveness, and sufficient reactivity from the standpoints of fine and natural product synthesis and process chemistry. Representative examples of the synthetic utility of acyclic (E)- and (Z)-stereodefined enol sulfonates are addressed as follows.

The Merck process group disclosed a characteristic protocol for (E)- and (Z)-stereocomplementary enol tosylations of specific α- or γ-nitrogen-substituted β-keto esters using respective Ts₂O–M(Li or Na)HMDS and Ts₂O–amine reagents.² The obtained stereodefined enol tosylate scaffolds were successfully subjected to stereoretentive Suzuki–Miyaura (SM) cross-couplings for the synthesis of various pharmaceutical precursors.

As part of our ongoing studies on mild but powerful sulfonylations³ and silylations⁴ of various alcohols and carbonyl compounds, we previously presented a series of (E)- and (Z)-stereocomplementary enol tosylations of not only acyclic α-nonsubstituted β-keto esters (R¹ = alkyl or aryl, R² = H), but also α-formyl esters (R¹ = H, R² = alkyl or aryl), which were conducted by the TsCl–N-methylimidazole (NMI)–base system (Scheme 1). TsCl–NMI–Et₃N was used for the (E)-selective reactions, whereas TsCl–NMI–LiOH controlled the (Z)-selective reactions. Subsequent highly (E)- and (Z)-stereoretentive cross-couplings (Negishi,⁵a Sonogashira,⁵a SM,⁵b,d and Kochi–Fürstner⁵c) were successfully performed to produce the corresponding stereodefined α,β-unsaturated esters. The current privileged robust and cost-effective protocols have been adopted for the synthesis of elaborated natural and unnatural compounds, such as juvenile hormones 0 and 1,⁵ab functionalized steroids,⁵c madangamine A,⁵d (E)- and (Z)-zimelidines,⁵d etc.

Very recently, the Merck process group reported a synthesis of chiral β-cyclopropyl-α-methylhydrocinnamates.⁶ This notable pharmacophore was synthesized via (E)- and (Z)-stereocomplementary enol tosylations using a β-cyclopropyl-α-methyl-β-keto ester; the (E)-isomer was prepared using Ts₂O–NaHMDS at –78 °C, whereas the (Z)-isomer was prepared using the same reagent at room temperature.

On the other hand, our group recently reported (E)- and (Z)-stereocomplementary enol phosphorylations of α-substituted β-keto esters as a relevant approach;⁷ the (PhO)₃POCl–NMI–LiOt-Bu reagent being used for preparing (E)-isomers, whereas the (PhO)₃POCl–NMI–KOT-Bu–18-
The (Z)-isomers. The application of this protocol to (E)- and (Z)-stereoretentive SM and Negishi cross-couplings produced the corresponding stereodefined all-carbon (fully) substituted α,β-unsaturated esters. This approach, however, has several conspicuous drawbacks compared with the reaction sequence via the enol tosylations; these include: (i) harsher reaction conditions (DMF, reflux) for the SM cross-coupling due to the poor reactivity of the (PhO)2PO- group, (ii) lower atom economy of the (PhO)2PO- group, (iii) a considerably more tedious separation procedure of (E)- and (Z)-enol phosphonates by column chromatography due to their similar Rf values, and (iv) stoichiometric amounts of expensive and highly toxic 18-crown-6 are required.

This background prompted us to search for a more efficient enol tosylation method using less reactive ‘α-carbon-substituted’ β-keto esters 1 (R1, R2 = alkyl and/or aryl). We present herein a substrate-general and robust method for (E)- and (Z)-stereocomplementary enol tosylations of 1 using the TsCl–Me2N(CH2)6NMe2 reagent for (E)-enol tosylates (E)-2 and the TsCl–TMEDA–LiCl reagent for (Z)-enol tosylates (Z)-2.9

Our initial attempt was intentionally guided using stereocongested methyl 2-butyl-3-oxooctanoate (1a)10 as a much less reactive substrate probe (Table 1). As anticipated, the reported NMI-mediated method6 resulted in almost no reaction (Table 1, entries 1 and 2). Notably, the use of inexpensive Me2N(CH2)nNMe2 (n = 3 or 6)11 alone afforded posi-

tive results for the (E)-selective reaction to give the desired enol tosylate (E)-2a (Table 1, entries 3–5). When using TMEDA, less reactive alcohols are prone to resist the tosylation reaction concomitant with the side production of TsNMe₂ via Hoffmann degradation of TMEDA with TsCl. This information led us to use Me₂N(CH₂)₃NMe₂ (n = 3 or 6).

Optimization of the temperature and time (−15 °C, 1 h and 20–25 °C, 1 h) allowed for improvement in both the yield (74%) and the stereoselectivity (E/Z = >98:2) (Table 1, entry 6). The best solvent was MeCN; EtOAc, DMF, THF, and toluene were apparently inferior (Table 1, entry 7). On the other hand, the (Z)-selective reaction proceeded smoothly to give (Z)-2a in good yield (93%) with excellent stereoselectivity (E/Z = 2:>98) using the available combined reagent, TsCl–TMEDA–LiCl under very accessible conditions (0–5 °C, 1 h and 20–25 °C, 1 h) (Table 1, entry 8). The use of TMEDA produced satisfactory results eventually compared with Me₂N(CH₂)₃NMe₂ (n = 3 or 6) (Table 1, entries 8–12). EtOAc and toluene gave moderate yields and the best solvent was MeCN (Table 1, entries 8–10).

In the two cases using Et₃N and LHMDs, considerable amounts of the α-chlorinated by-product (methyl 2-butyl-2-chloro-3-oxyoctanoate) of 1a were detected (Table 1, entries 13 and 14). The occurrence of this side reaction is ascribed to the fact that TsCl cannot be sufficiently activated (vide infra, Scheme 4). Accordingly, the present method is obviously more efficient than the NMI-mediated reactions.

With the successful outcome in hand, Table 2 lists the substrate generality using a variety of α-substituted β-keto esters 1 (method A for (E)-isomers (E)-2 and method B for (Z)-isomers (Z)-2). The salient features are as follows. (i) All reactions were completed under the identical optimized conditions in good to excellent yield. (ii) With regard to stereoselectivity, almost all cases produced positive and excellent results (>94:6 for method A and 2:>98 for method B). (iii) As a limitation, the (E)-selectivity using α,β-dialky substrates (E)-1j and (E)-1k was moderate (Table 2, entries 19 and 21). This tendency coincides with discussions in the precedent report which ascribes to the nature of intrinsically more stable (Z)-isomers. Fortunately, these crude products could be enriched to the pure (E)-products, (E)-2j and (E)-2k, by recrystallization. It should be noted that all of these stereodefined (E)- and (Z)-enol tosylates 2 are novel compounds.

Next, an extension to α-heteroatom (MeO and Cl) substituted β-keto esters 1l and 1m was examined (Scheme 2). Gratifyingly, the reactions proceeded smoothly to give the desired functionalized products (E)-, (Z)-2l and (E)-, (Z)-2m. (Note: due to the sequence rule, reverse configurations are indicated.)
shifts of the tosyl moiety in IA are related to the higher reactivity of the present system. Based on the result, IA is likely to function as the key active species\textsuperscript{15,16}.

In conclusion, we have developed a general and convenient protocol for (E)\textsuperscript{-} and (Z)\textsuperscript{-}stereocomplementary enol tosylation of α-substituted β-keto esters using the TsCl–Me\textsubscript{2}N(CH\textsubscript{2})\textsubscript{6}NMe\textsubscript{2} reagent (method A) and the TsCl–TMEDA–LiCl reagent (method B), respectively. A plausible mechanism for the successful (E)\textsuperscript{-} and (Z)\textsuperscript{-}enol tosylation selectivity is proposed. A \textsuperscript{1}H NMR monitoring experiment revealed that TsCl coupled with TMEDA formed a simple N-sulfonylammonium intermediate. Further investigation on various (E)\textsuperscript{-} and (Z)\textsuperscript{-}stereoretentive cross-couplings using the obtained fully substituted enol tosylates, a pair of latent and potential scaffolds, is now under progress in our laboratory.

### Table 2  (E)\textsuperscript{-} and (Z)\textsuperscript{-}Stereo complementary Enol Tosylation of 1 Using TsCl–Me\textsubscript{2}N(CH\textsubscript{2})\textsubscript{6}NMe\textsubscript{2} (Method A) and TsCl–TMEDA–LiCl (Method B)

\textsuperscript{a} Determined by \textsuperscript{1}H NMR of the crude products.
\textsuperscript{b} TsCl (3.0 equiv) and Me\textsubscript{2}N(CH\textsubscript{2})\textsubscript{6}NMe\textsubscript{2} (3.0 equiv) were used.
\textsuperscript{c} TsCl (3.0 equiv), TMEDA (3.0 equiv), and LiCl (3.0 equiv) were used.
\textsuperscript{d} Yield after recrystallization; see the experimental section for details.
All reactions were carried out in oven-dried glassware under an argon atmosphere. Flash column chromatography was performed with silica gel (Merck 60, 230–400 mesh ASTM). TLC analysis was performed on 0.25 mm silica gel Merck 60 F254 plates. Melting points were determined on a hot stage microscope apparatus (AS ONE, ATM-01) and are uncorrected. IR spectra were recorded on a JASCO FT/IR-5300 spectrophotometer. NMR spectra were recorded on a JEOL DELTA 300 or JEOLRESONANCE ECX-500 spectrometer, operating at 300 MHz or 500 MHz for $^1$H NMR and 75 MHz or 125 MHz for $^{13}$C NMR. Chemical shifts (δ) (ppm) in CDCl$_3$ are reported downfield from TMS (0 ppm) for $^1$H NMR. For $^{13}$C NMR, chemical shifts are reported relative to CDCl$_3$ (77.00 ppm) as an internal reference. Mass spectra were measured on a JEOL JMS-T100LC spectrometer. $\beta$-Keto esters 1a, 1b, 1c, 1d, 1e, 1g, 1h, 1i, and 1j are known compounds, whilst 1f, 1k, and 1m are new compounds and were prepared by Ti-Claisen condensation or alkylation in a single step and on gram scale. Detailed procedures and physical and spectroscopic data are described in the Supporting Information.

(E)-Enol Tosylation of $\beta$-Keto Esters (Method A); General Procedure

TsCl (286 mg, 1.50 mmol) in MeCN (1.0 mL) was added to a stirred suspension of a $\beta$-keto ester (1.00 mmol) and Me$_2$N(CH$_2$)$_6$NMe$_2$ (258 mg, 1.50 mmol) in MeCN (1.0 mL) at −15 °C, and the mixture was stirred at the same temperature for 1 h and at 20–25 °C for 1 h. H$_2$O (a large amount) was added to the mixture, which was extracted twice with EtOAc. The combined organic phase was washed with H$_2$O, sat. aq NaHCO$_3$ solution and brine, then dried (Na$_2$SO$_4$), and concentrated. The obtained crude product was purified by SiO$_2$ column chromatography (hexane/EtOAc = 50:1 to 15:1) to give the desired product.

(Z)-Enol Tosylations of $\beta$-Keto Esters (Method B); General Procedure

TsCl (286 mg, 1.50 mmol) in MeCN (1.0 mL) was added to a stirred suspension of a $\beta$-keto ester (1.00 mmol), TMEDA (258 mg, 1.50 mmol), and LiCl (64 mg, 1.50 mmol) in MeCN (1.0 mL) at 0–5 °C, and the mixture was stirred at the same temperature for 1 h and at 20–25 °C for 1 h. H$_2$O (a large amount) was added to the mixture, which was extracted twice with EtOAc. The combined organic phase was washed with H$_2$O, sat. aq NaHCO$_3$ solution and brine, then dried (Na$_2$SO$_4$), and concentrated. The obtained crude product was purified by SiO$_2$ column chromatography (hexane/EtOAc = 50:1 to 10:1) to give the desired product.

(E)-2a (Method A); Typical Gram-Scale Procedure

TsCl (4.29 g, 22.5 mmol) in MeCN (15 mL) was added to a stirred suspension of methyl 2-butyl-3-oxooctanoate (1a) (3.42 g, 15.0 mmol) and Me$_2$N(CH$_2$)$_6$NMe$_2$ (4.85 mL, 22.5 mmol) in MeCN (15 mL) at 0–5 °C, and the mixture was stirred at the same temperature for 1 h and at 20–25 °C for 1 h. H$_2$O was added to the mixture, which was extracted twice with EtOAc. The combined organic phase was washed with H$_2$O, sat. aq NaHCO$_3$ solution and brine, then dried (Na$_2$SO$_4$), and concentrated. The obtained crude product was purified by SiO$_2$ column chromatography (hexane/EtOAc = 15:1) to give the desired product (E)-2a (3.46 g, 60%, E/Z = >98/2).

(Z)-2a (Method B); Typical Gram-Scale Procedure

TsCl (4.29 g, 22.5 mmol) in MeCN (15 mL) was added to a stirred suspension of methyl 2-butyl-3-oxooctanoate (1a) (3.42 g, 15.0 mmol), TMEDA (3.35 mL, 22.5 mmol), and LiCl (954 mg, 22.5 mmol) in MeCN (15 mL) at 0–5 °C, and the mixture was stirred at the same temperature for 1 h and at 20–25 °C for 1 h. H$_2$O was added to the mixture, which was extracted twice with EtOAc. The combined organic phase was washed with H$_2$O, sat. aq NaHCO$_3$ solution and brine, then dried (Na$_2$SO$_4$), and concentrated. The obtained crude product was purified by SiO$_2$ column chromatography (hexane/EtOAc = 10:1) to give the desired product (Z)-2a (4.74 g, 82%, E/Z = 2/98).

**IR** (neat): 1732, 1595, 1489, 1435, 1314, 1248, 1161 cm⁻¹.

**1H NMR (500 MHz, CDCl₃):** δ = 2.03 (s, 3 H), 2.36 (s, 3 H), 3.51 (s, 3 H), 4.74–5.46 (m, 2 H).

**13C NMR (75 MHz, CDCl₃):** δ = 14.8, 21.5, 51.8, 123.1, 127.6 (2 C), 127.8 (2 C), 128.7 (2 C), 129.2, 129.3 (2 C), 133.4, 133.8, 144.8, 151.6, 164.8.

**HRMS (ESI):** m/z [M + Na]^+ calcd for C_{18}H_{17}O_{5}Na: 439.0674; found: 439.0675.
Methyl (E)-2,3-Diphenyl-3-(tosyloxy)prop-2-enoate [(E)-2j]

Yield: 3.91 g (96%); pale yellow oil.

IR (neat): 2959, 2866, 1724, 1615, 1384, 1262, 1180, 1047 cm⁻¹.

Methyl (E)-2-Chloro-3-(tosyloxy)oct-2-enoate [(E)-2l]

Yield: 261 mg (62%); colorless oil.

IR (neat): 2955, 2862, 1734, 1622, 1597, 1384, 1208 cm⁻¹.

Acknowledgment

This research was partially supported by Grant-in-Aids for Scientific Research on Basic Areas (B) ‘18350056’, Priority Areas (A) ‘17035087’ and ‘18030768’, and Exploratory Research ‘17655045’ from the Ministry of Education, Culture, Sports, Science and Technology (MEXT).

Supporting Information

Supporting information for this article is available online at http://dx.doi.org/10.1055/s-0035-1562482.
References

(9) The use of LiCl instead of LiOH was also applied by Shinada’s group; see refs. 6a and 6b.

(10) The 50 gram-scale preparation of 1a was performed by the self Ti-Claisen condensation using methyl hexanoate with TiCl4 and Et2N at 0–5 °C for 1 h (93% yield); see the Supporting Information and ref. 8.

(11) TMEDA: $80/500 g; Me2N(CH2)3NMe2: ca. $110/500 g; Me2N(CH2)6NMe2: ca. $90/500 g. Reagent base.

(12) After finishing this work, EtOAc and toluene were available for reactive not fully, trisubstituted substrates.

(13) This issue is addressed in ref. 2a. To solve the problem, presumably, the Merck group consistently uses reactive but highly expensive Ts2O instead of TsCl.

(14) This monitoring study resembles the case of TsCl–NMI (see refs. 5a and 5d) and (PhO)2POCl–NMI (see ref. 8) intermediates.

(15) A related monitoring experiment using p-MeC6H4COCl with TMEDA was carried out in our hands; noticeable changes of 1H NMR spectra were not observed under the identical conditions. The interactive action of TsCl, therefore, may be stronger than that of benzoyl chlorides.
