

Ruthenium-Catalyzed Cycloaddition of Benzocyclobutenes with Diols

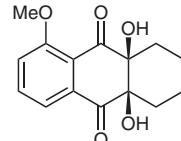

Selected examples:

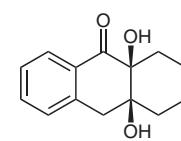

88% yield, dr > 20:1

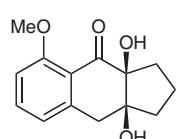

82% yield, dr > 20:1

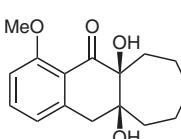

89% yield, dr > 20:1

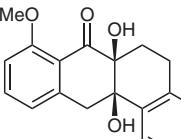

95% yield, dr > 20:1

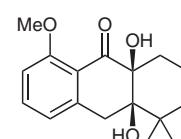

64% yield, dr > 20:1

82% yield, dr > 20:1

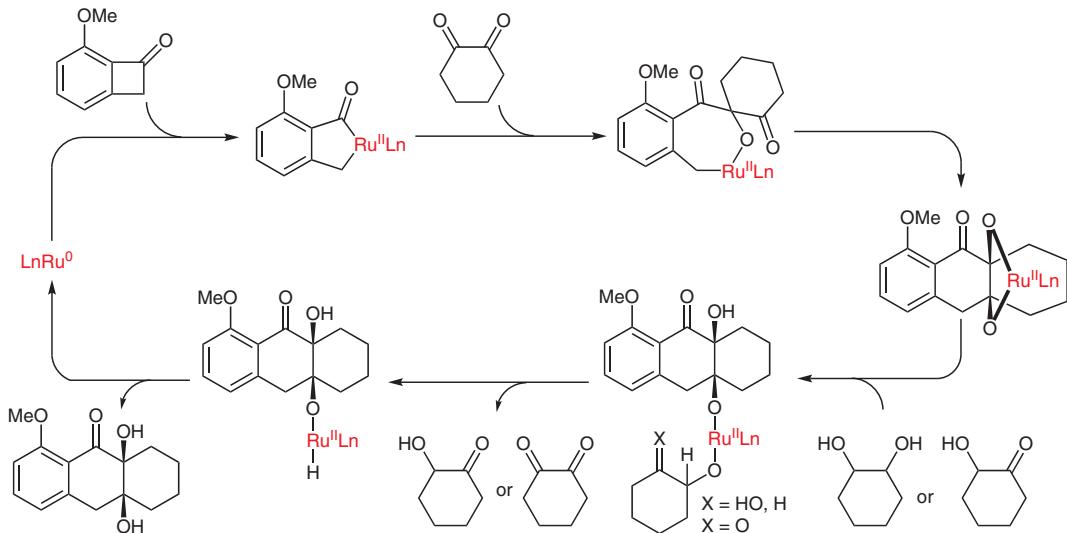

86% yield, dr > 20:1
single regioisomer

61% yield, dr > 20:1
single regioisomer

Proposed mechanism:

Significance: The authors have reported intermolecular cycloadditions through formal insertion of saturated C–H bonds into C–C σ-bonds. A ruthenium(0)/dppp complex catalyzed the diastereoselective coupling reactions of benzocyclobutenones to adjacent saturated carbon centers in diols.

SYNFACTS Contributors: Hisashi Yamamoto, Takahiro Sawano

Comment: The cycloaddition via ruthenacycles from the benzocyclobutenones and dehydrogenation of the alcohols provides a convergent method for the construction of type II polyketide substructures.
