Abstract A sequential benzoylation and multihetero-Cope rearrangement of α-keto ester derived nitrones has been developed. The reaction furnishes a diverse array of complex α-imino ester derivatives. The products can be transformed into amino alcohols via LiAlH4 reduction.

Key words rearrangement, ketones, imines, oxygenations, esters

Fragmentation of weak N–O σ-bonds (bond strength ~57 kcal/mol) can be leveraged during the synthesis of complex organic frameworks, and a comprehensive review of the rearrangement of N-oxyenamine derivatives has been penned by Tabolin and Ioffe.3 Within this subclass of N–O bond-breaking reactions, sigmatropic rearrangements of O-acetyl- and O-imidoyl-N-oxyenamines can provide α-hydroxy or α-amino carbonyl derivatives, which are valuable intermediates and key structural elements of natural and unnatural bioactive compounds. An early report by Coates and Cummins provided a method for the rearrangement of N-vinyl-O-acetylanilines resulting from acylation of nitrones with acid chlorides (Scheme 1, a).4 More recently, Tomkinson and co-workers disclosed the design of N-alkyl-O-acetylanilines that facilitate the synthesis of α-hydroxy carbonyl derivatives by way of a tandem condensation/rearrangement process (Scheme 1, b).5 Alternatively, the use of a Cbz-protected trifluoromethyl imidoyl chloride led to α-amination of nitrones analogous to the α-oxygenation developed by Coates (Scheme 1, c).6 The development of methods for the synthesis of β-branched α-keto esters is a topic of ongoing interest,7–9 and the functionalization of such compounds via N-oxyenamine rearrangements appealed to us as a means to generate complex α-imino esters containing fully substituted β-stereocenters (Scheme 1, d). Following rearrangement, the C=N π-bond could, in principle, react with nucleophiles, providing access to novel amino acid derivatives possessing contiguous stereocenters.

We initially chose to focus on the β-benzoylation of α-keto ester derived O-benzoyl-N-oxyenamines. We first tested condensation of α-keto ester 1a with the Tomkinson reagent A (Table 1, entry 1). Presumably this reaction was

prevented by the sterically hindered ketone of 1a coupled with low nucleophilicity of the free base of A. Heating a mixture of N-benzylhydroxylamine and α-keto ester 1a furnished nitrone 2a, which upon treatment with benzoyl chloride (B) in the presence of triethylamine and the nucleophilic catalyst 4-(dimethylamino)pyridine (DMAP) delivered the desired β-benzoylated imino ester 3a in 48% yield (Table 1, entry 2). In this experiment, the corresponding α-keto ester resulting from hydrolysis of 3a by adventitious water was observed in the 1H NMR spectrum of the unpurified materials. Sequestration of acid is apparently crucial to the stability of 3a under the reaction conditions as replacing triethylamine with the thermodynamically stronger base Proton-sponge® suppresses hydrolysis, allowing isolation of 3a in 86% yield (Table 1, entry 3). Despite the sensitivity of 3a under the conditions, it is completely stable toward chromatography on untreated silica gel. The reaction proceeds in the absence of DMAP, however the yield of 3a is lower (Table 1, entry 4).

With suitable reaction conditions in hand, we began to explore the scope of α-imino esters that could be prepared (Scheme 2). The p-halogen series imines 3b–d were obtained in high yield. In addition, an α-fluoro-substituted nitrone underwent the reaction in good yield to afford imino benzoate 3e. Electron-rich nitrones were also viable substrates, and representative examples include imines 3f–3h.

In summary, we have developed a sequential benzylation–multihetero-Cope rearrangement of α-keto ester derived nitrones. The reaction furnishes complex α-imino ester derivatives in good to excellent yield. The products can be transformed into complex amino alcohols via LiAlH₄ reduction. Further exploration of the reactivity of these products, with a particular focus on accessing complex amino acid derivatives via selective functionalization of the imine moiety, is currently underway in our laboratory.

Larger alkyl substituents were tolerated at the β-position, and β-benzyl-substituted tertiary benzoate 3i as well as the ethyl derivative 3j could be obtained in good and moderate yield, respectively. Other aroyl chlorides could also be used in the reaction, and p-methylbenzoate 3n, m-chlorobenzoate 3o, as well as o-bromobenzoate 3p were obtained in high yield.

Preliminary attempts to selectively functionalize the azomethine functionality in the rearrangement products have been unsuccessful, most likely due to the sterically encumbered nature of these electrophiles. At this stage, the utility of the products has been demonstrated by exhaustive LiAlH₄ reduction of 3a and 3f, which delivered the corresponding amino alcohols 4a and 4f in intermediate yield and diastereoselectivity (Scheme 3). The relative stereochemistry of the major diastereomer was established via synthesis of the cyclic carbamate 5f, which exhibited the illustrated NOESY interactions between the methyl protons and the methine proton.

Unless noted otherwise, all experiments were carried out in a flame-dried round-bottomed flask under a stream of nitrogen gas. H and ¹³C NMR spectra were obtained on a Bruker DRX 600 (¹H, 600 MHz; ¹³C, 150 MHz), Bruker 500 (¹H, 500 MHz; ¹³C, 125 MHz), or Bruker DRX 400 (¹H, 400 MHz; ¹³C, 100 MHz) spectrometer. ¹H NMR data are reported as follows: chemical shift, multiplicity (standard abbreviations), coupling constant(s) (Hz), and relative integration. For HRMS, all samples were prepared in MeOH. The HPLC system consisted of an Agilent 1200 binary pump (G1312A) operating at a flow rate of 0.3 mL·min⁻¹. The solvents were degassed using an on-line membrane system (Agilent G1379A). The column was maintained in a thermostated compartment at 40 °C (Agilent G1316A). The diode array detector (Agilent G1315D) was operated at three wavelengths (250, 254, and 280 nm). Separation was performed on a Waters Acquity UPLC BEH C18 column (2.1 × 50 mm, 1.7 μm particle size). The injection (5 μL) was performed using an autosampler (Agilent G1329A). LC conditions were set at water with 0.1% formic acid (A) for 1 min, before ramping linearly over 5 min to 100% acetonitrile with 0.1% formic acid (B), and then switched back to 100% A and allowed to re-equilibrate until 10 min. The HPLC system was coupled to the Q-TOF system via a dual ESI interface operating in positive ion mode using a capillary voltage of +3.5 kV. The other optimum values of the ESI-TOF parameters were drying gas temperature 325 °C, drying gas flow 5 l/min⁻¹, and nebulizing gas pressure 15 psi. Detection was carried out considering a mass range of 100–1500 m/z. Prior to acquiring samples, an external instrument calibration was performed using Agilent ESI-L Low Concentration Tuning Mix. MassHunter Quantitative Analysis (Agilent) was used to analyze the data. Solutions were dissolved in MeOH at 0.1 mg·mL⁻¹ or less, and diluted appropriately based on responsiveness to the ESI mechanism. Molecular formula assignments were determined with Molecular Formula Calculator (v 1.2.3). The success of mass data for molecular ions was considered based on the widely accepted accuracy threshold for confirmation of elemental compositions established at 5 ppm. All observed species were singly charged, as verified by unit m/z separation between mass spectral peaks corresponding to the ¹²C and ¹³C⁺⁺ isotopes for each elemental composition. IR spectra were obtained using a Jasco 460 Plus Fourier transform infrared spectrometer. TLC was performed on Sorbtech plastic-backed 0.20 mm silica gel 60 plates. Visualization was accomplished with UV light and either an aqueous ceric ammonium molybdate (CAM) or KMnO₄ solution, followed by heating. Flash chromatography was performed under positive nitrogen pressure using SiliaFlash-P60 silica gel (40–63 μm) purchased from Silicycle. Et₂N was purified and dried by passing through a column of activated alumina. DMAP and BuOH were purchased from Sigma-Aldrich and used without further purification. Benzoyl chloride was purchased from Acros and used without further purification. Methyl tert-butyl ether (MTBE) was purified via distillation from calcium hydride and stored over activated 13X-type molecular sieves (bead form). The pro-

**tert-Butyl α-Keto Esters**; General Procedure

Step 1: The ethyl 2-oxo-3-arylbutanoate (4.46 mmol), prepared in two steps via a literature method,\(^{11}\) was added neat to a 25-mL round-bottomed flask equipped with a stir bar. Next, aqueous NaOH (3 M, 4 mL) was added and the reaction mixture was stirred for 24 h at rt. The mixture was then acidified (pH ~5) with aqueous HCl (3 M), and the aqueous layer was extracted with CH\(_2\)Cl\(_2\) (3 × 15 mL). The combined organic layers were dried over MgSO\(_4\). Filtration through a plug of cotton and concentration delivered the corresponding α-keto acid which was carried on without purification. Step 2: The crude α-keto acid from step 1 was dissolved in CH\(_2\)Cl\(_2\) (4.5 mL), and several small drops of DMF were added. The reaction mixture was cooled to 0 °C using an ice–water bath, and oxalyl chloride (0.57 mL, 6.69 mmol, 1.5 equiv) was slowly added. The reaction mixture was stirred for 20 h and concentrated. Residual oxalyl chloride was removed under reduced pressure. The acid chloride was immediately used in the next step without purification. Step 3: 'BuOH (1.27 mL, 13.4 mmol, 3.0 equiv) and pyridine (719 μL, 8.92 mmol, 2.0 equiv) were dissolved in CH\(_2\)Cl\(_2\) (4.5 mL, 1 M), and the mixture was cooled to 0 °C using an ice–water bath. The acid chloride from step 2 was slowly added in CH\(_2\)Cl\(_2\) (1.96 mL, 2.3 M). The reaction mixture was stirred for 24 h, then diluted with water. The aqueous phase was extracted three times with CH\(_2\)Cl\(_2\) (20 mL), and the combined organic layers were dried over MgSO\(_4\). The product was purified by silica gel column chromatography.

syringe. The mixture was stirred for approximately 15 min at room temperature and initiation of Grignard formation was not observed. The flask was heated using a heat gun to initiate Grignard formation. Once the magnesium turnings had been visibly consumed, the solution of the Grignard reagent was added dropwise to a separate solution of tert-butyl 2-(1H-imidazo[1-1]-y)-2-oxoacetate in THF (25.4 mL) that had been pre-cooled to -78 °C using a dry ice/acetone bath. The resulting mixture was allowed to stir at -78 °C for 1 h prior to being quenched at -78 °C with 10 mL of 1M HCl. Upon warming to room temperature, the reaction mixture was quenched with 40 mL of water, and the aqueous phase was extracted several times with diethyl ether. syn-2-(Benzyllimino)-3-(4-methoxyphenyl)butane-1,3-diol (4f)
via LiAlH₄ Reduction; Typical Procedure

α-Limino ester 3f (248 mg, 0.52 mmol) was dissolved in THF (3.50 mL). The resulting solution was cooled in an ice bath, and LiAlH₄ (2 M in THF, 2.10 mL, 8.0 equiv) was slowly added. The reaction mixture was stirred for 12 h, and then quenched with saturated aqueous sodium sulfate until gas evolution had ceased. The resulting mixture was passed through a plug of Celite using EtOAc to rinse. The resulting product was purified by silica gel column chromatography using 30% and then 50% EtOAc/hexanes to give the major diastereomer of 4f (87.5 mg isolated, 56% yield).

1H NMR (500 MHz, CDCl3): δ = 7.26–7.35 (m, 7 H), 6.86–6.88 (m, 2 H), 3.95 (d, J = 13.0 Hz, 1 H), 3.88 (d, J = 13.0 Hz, 1 H), 3.80 (s, 3 H), 3.50 (dd, J = 4.4, 11.5 Hz, 1 H), 3.42 (dd, J = 3.4, 11.5 Hz, 1 H), 2.75–2.77 (m, 1 H), 1.59 (s, 3 H).

HRMS (ESI): m/z calcld for C14H18O6 [M + H]: 290.13; found: 290.13.

syn-2-(Benzyllimino)-3-phenylbutane-1,3-diol (4a)
α-Limino ester 3a (146 mg, 0.32 mmol) was used as starting material, to give the major diastereomer of 4a (51.8 mg isolated, 58% yield).

1H NMR (600 MHz, CDCl3): δ = 7.39–7.40 (m, 2 H), 7.33–7.36 (m, 6 H), 7.25–7.30 (m, 2 H), 3.96 (d, J = 13.0 Hz, 1 H), 3.88 (d, J = 13.0 Hz, 1 H), 3.48 (dd, J = 4.1, 11.5 Hz, 1 H), 3.37 (dd, J = 3.3, 11.5 Hz, 1 H), 2.78–2.80 (m, 1 H), 1.61 (s, 3 H).

13C NMR (150 MHz, CDCl3): δ = 145.8, 140.0, 128.5, 128.3, 128.2, 127.2, 126.8, 124.7, 77.1, 64.9, 61.1, 53.4, 27.9.

(z)-(2R,3S)-3-(Benzyllimino)-4-(tert-butyldimethylsilyloxy)-2-(4-methoxyphenyl)butan-2-ol (z-S1)
A flame-dried vial was cooled under N₂, and charged with alcohol (z)-4f (34.0 mg, 0.113 mmol, 1 equiv), imidazole (23.0 mg, 0.338 mmol, 3 equiv), and CH₂Cl₂ (1 mL). The solution was cooled to 0 °C, and TBSCI (37.4 mg, 0.248 mmol, 2.2 equiv) was added. The reaction mixture was allowed to warm to rt slowly overnight, and stirred for a total of 16 h. The reaction mixture was passed through a plug of silica gel, and the plug was washed with EtOAc (3 × 2 mL), then concentrated. The crude product was purified by silica gel column chromatography (EtOAc/hexanes, 10:90), which afforded (z)-S1 (39.0 mg, 83% yield) as a clear and colorless liquid.

Rₛ = 0.2 (EtOAc/hexane, 10:90).

1H NMR (600 MHz, CDCl3): δ = 7.28–7.37 (m, 7 H), 6.84 (d, J = 7.3 Hz, 2 H), 3.95 (d, J = 13.0 Hz, 1 H), 3.75–3.82 (m, 4 H), 3.57 (dd, J = 10.4, 3.9 Hz, 1 H), 3.34 (app d, J = 8.1 Hz, 1 H), 2.76 (br s, 1 H), 1.59 (s, 3 H), 0.86 (s, 9 H), –0.01 (s, 3 H), –0.05 (s, 3 H).

(z)-(4S,5R)-3-Benzyl-4-(((tert-butyldimethylsilyloxy)methyl)-5-(4-methoxyphenyl)-5-methyloxazolidin-2-one (z-5f)
A flame-dried vial was cooled under N₂, and charged with amino alcohol (z)-S1 (34.0 mg, 0.0828 mmol, 1 equiv), THF (0.5 mL), and Et₃N (34 µL, 0.245 mmol, 3 equiv). The solution was cooled to 0 °C, and a solution of triphosgene (29.1 mg, 0.0982 mmol, 1.2 equiv) in THF (1 mL) was added dropwise. The reaction mixture was allowed to warm to rt slowly overnight, and stirred for a total of 16 h. The reaction mixture was diluted with saturated aqueous ammonium chloride (1 mL), and stirred for 30 min. The reaction mixture was added to a separatory funnel, and diluted with CH₂Cl₂ (30 mL) and saturated aqueous ammonium chloride (30 mL). The layers were separated, and the organic layer was collected. The aqueous layer was extracted with CH₂Cl₂ (2 × 30 mL), and the combined organic extracts were dried over Na₂SO₄, filtered, and concentrated. The crude product was purified by silica gel column chromatography (EtOAc/hexanes, 10:90 to 15:85), which afforded (z)-5f (32.9 mg, 91% yield) as a clear and colorless liquid.

Rₛ = 0.15 (EtOAc/hexane, 10:90).
1H NMR (600 MHz, CDCl3): δ = 7.34–7.39 (m, 2 H), 7.30–7.35 (m, 3 H), 7.23–7.28 (m, 2 H), 6.85 (d, J = 8.8 Hz, 2 H), 4.98 (d, J = 15.0 Hz, 1 H), 4.09 (d, J = 15.0 Hz, 1 H), 3.80 (s, 3 H), 3.39 (app t, J = 4.1 Hz, 1 H), 3.25 (app qd, J = 11.0, 4.2 Hz, 2 H), 1.63 (s, 3 H), 0.80 (s, 9 H), −0.15 (s, 3 H), −0.26 (s, 3 H).
