Abstract The first total synthesis of natural (+)-cycloclavine uses a catalytic asymmetric cyclopropanation of allene, a regiospecific Pd-catalyzed enone formation, and two intramolecular Diels–Alder reactions for indole/indoline annulations. The binding properties of natural (+)– and unnatural (–)-cycloclavine on 16 CNS receptors revealed significant stereospecificity and unique binding profiles in comparison to LSD, psilocin, and DMT. Differential 5-HT affinities, as well as novel sigma-1 receptor properties bode well for potential therapeutic developments of clavine alkaloid scaffolds.

Key words clavine ergot alkaloids, enantioselective allene cyclopropanation, psychedelics, stereospecific GPCR binding, LSD, psilocin, DMT, 5-HTA, sigma-1 receptors

While the unique properties of naturally occurring compounds have always fascinated researchers from all branches of Science, the total synthesis of alkaloids currently experiences a remarkable renaissance, motivated by the complex architectures, diverse functionalities, and profound biological and cultural impact of this large family of natural products.1 Indole alkaloids, in particular, are attracting significant attention in Chemistry and Medicine.2

With the goal to explore both innovative synthetic strategies and new biological applications, we have recently established a program in the total synthesis of ergot alkaloids of the clavine and lysergic acid subclasses (Figure 1).3

In 1969, A. Hofmann and co-workers at Sandoz in Basel, Switzerland, reported the isolation of a novel, cyclopropane-containing ergot alkaloid, (+)-cycloclavine, from the seeds of the morning glory Ipomoea hildebrandtii VAT-KE, collected in Nairobi, Kenya.4 After a latency of almost 40 years, cycloclavine has now become a popular target for organic synthesis, and a number of groups have reported innovative synthetic approaches. In pioneering studies from the group of Szántay, 4-bromo-Uhle’s ketone was subjected to an alkylation and intramolecular aldol reaction for indole/indoline annulations. The binding properties of natural (+)- and unnatural (–)-cycloclavine on 16 CNS receptors revealed significant stereospecificity and unique binding profiles in comparison to LSD, psilocin, and DMT. Differential 5-HT affinities, as well as novel sigma-1 receptor properties bode well for potential therapeutic developments of clavine alkaloid scaffolds.

Figure 1 Examples of naturally occurring ergot alkaloids
oped two formal syntheses of racemic cycloclavine and a formal synthesis of (+)-cycloclavine starting from substituted indoles and intersecting with the late stage alkene in Szántay’s synthesis.9

Another formal synthesis of (±)-cycloclavine that converged with Szántay’s approach was accomplished by Netz and Opatz in 2016, utilizing a γ-alkylation of a pyrrolinone followed by a Heck coupling.10

The first asymmetric synthesis of (–)-cycloclavine, the enantiomer of the natural alkaloid, was accomplished by our group in 2017.11 Key features of this synthesis were a catalytic asymmetric cyclopropanation of allene, an intramolecular Diels–Alder reaction to methylenecyclopropane (IMDAMC), and an intramolecular Diels–Alder reaction to furan (IMDAF). Subsequently, a formal synthesis of both enantiomers of cycloclavine was realized by Bisai and co-workers based on a D- or L-proline catalyzed α-aminooxalylation and a Heck coupling (Scheme 2).12 Most recently, Dong and co-workers developed a benzyne cycloaddition/alkene carboacylation route to both (–)-5-epi-cycloclavine and (–)-cycloclavine, utilizing a ring-enlargement of a benzocyclobutenone intermediate as a key reaction.13

Our retrosynthetic analysis is summarized in Scheme 3. In analogy to our route to (–)-cycloclavine,11 we selected an asymmetric rhodium-catalyzed cyclopropanation of allene with a diazopropanoate active ester, followed by an aminoysis with 4-(methylamino)but-3-en-2-one, for the assembly of the key precursor for the IMDAMC reaction. After installing the enone in the six-membered ring by a Diao–Stahl ketone dehydrogenation,14 the thermally removable Tempoc group for amine protection15 would be used to stabilize an aminomethylithium reagent and favor enone 1,2-addition versus lactam ring opening. The final indole ring fusion was envisioned to be accomplished by the IMDAF cycloaddition.16b,d,f,7,16

**Biographical Sketches**

**Stephanie R. McCabe** received her B.Sc. (Honours) in 2012 from the Australian National University, conducting research under the supervision of Professor Martin Banwell. In 2018, she obtained her Ph.D. in the Wipf group at the University of Pittsburgh. Her research interests centered on natural product total synthesis.

**Peter Wipf** received his Ph.D. in 1987 from the University of Zürich under the direction of Professor Heinz Heimgartner. He then joined the laboratory of Professor Robert E. Ireland at the University of Virginia as a Swiss NSF postdoctoral fellow, and, in 1990, the University of Pittsburgh as an Assistant Professor. Since 2004, he is the Distinguished University Professor of Chemistry at the University of Pittsburgh. Wipf’s research focuses on the total synthesis of natural products, organometallic, heterocyclic and medicinal chemistry.
For the realization of this retrosynthetic plan, two building blocks and a chiral ligand needed to be prepared and optimized at the onset of the synthesis. The condensation of pyruvic acid (2) with tosyl hydrazide (1) under acidic conditions provided hydrazone 3 in 93% yield (Scheme 4). Treatment with oxalyl chloride and esterification of the resulting acid chloride with pentafluorophenol (PfOH) delivered an active ester intermediate suitable for rapid segment assembly. Base-mediated diazo formation produced the first building block 4 in 21% yield.

Next, we focused on the selection of an appropriate transition metal catalyst and chiral ligand for the asymmetric allene cyclopropanation step. Diazopropanoates 5 are challenging reagents for use in metal-mediated cyclopropanations because of the propensity of the metal carbenoid to undergo competing β-hydride migration to form an acrylic ester 7 (Scheme 5). In the past decade, several methods have emerged that address this limitation. Fox et al. found that dirhodium complexes with sterically hindered carboxylate ligands in conjunction with low reaction temperatures effectively promoted intermolecular cyclopropanations over the competing β-H migration pathway.17

Among the enantioselective variants, bulky carboxylates derived from L-tert-leucine, such as Rh₄(S-PTTL)₄ (8), were found to be particularly effective. More recently,
Hashimoto et al. showed that the substrate scope could be further expanded when the dirhodium complex Rh₂(η-S-TBPTTL₄)₄ (9) was used as the catalyst (Figure 2).¹⁸ We also prepared the enantiomer of 9, Rh₂(η-R-TBPTTL₄)₄ (10), from d-tert-leucine [(R)-18] and anhydride 17 in toluene at reflux, followed by a ligand exchange reaction with Rh₂(OAc)₄ in a chlorobenzene/MeCN mixture at 130 °C (Scheme 6). Furthermore, we reasoned that the 4,7-diphenyl substitution pattern on the phthalimide ring of the novel, sterically demanding dirhodium catalyst 11 would impose even greater steric discrimination than the corresponding bromide substituents in 9 and 10, hopefully leading to greater differentiation between the enantiotopic faces of the allene. This catalyst was prepared in a Diels-Alder reaction of diphenylbutadiene (19) and maleic anhydride (20), followed by DDQ oxidation to afford anhydride 21, which was reacted with (S)-18 in the presence of triethylamine to give 22 and subjected to a ligand exchange reaction to yield 11 (Scheme 7).

For further comparisons of ligand chemotypes, we decided to include an evaluation of the known dirhodium catalysts 12–14 (Figure 2).¹⁸ The ruthenium(II) complex 15 was added to this list because 15 was highly effective in related asymmetric cyclopropanations of mono- and disubstituted allenes with succinimimidyl diazoacetate.²⁰ Finally, the (salen)cobalt(II) catalyst 16 was also screened since Katsuki et al. showed that it was an excellent catalyst for the enantioselective cyclopropanation of styrenes with α-alkyl-diazoacetates.²¹

The results of the cyclopropanation of allene (23) with pentafluorophenyl diazopropanoate (4) to give methylene cyclopropane 24 in the presence of the chiral catalysts 8–16 are summarized in Table 1. Rh(II)-Catalysts with sterically hindered amino acid ligands but lacking phthalimide substituents, such as 8 and 12, provided a low e.r. of approximately 7:3 (Table 1, entries 1 and 5). Hashimoto’s tetrabromomethylenecyclopropane 9 resulted in a notable improvement, giving the cyclopropane (R)-24 in a high yield with an e.r. of 87:13 (entry 2). As expected, the (R)-tert-leucine derived 10 gave the enantiomeric product (S)-24 in identical yield and e.r. (entry 3). Disappointingly, however, virtually no enantioinduction was observed when allene was reacted with 4 in the presence of the sterically more demanding dirhodium catalyst 11 (product e.r. = 55:45, entry 4). With this catalyst, no reaction occurred at −78 °C and the mixture had to be warmed to −40 °C before conversion was observed. The chiral cyclopropane catalyst 13 delivered the desired product 24 in moderate yields and with poor enantioinduction (entry 6). Davies’ proline-based catalyst 14 also provided only a moderate yield of 61%, and negligible asymmetric induction (entry 7). The reaction of Ru(II)-catalyst 15 did not deliver any of the desired product. Instead, upon warming the reaction mixture from −78 °C to room temperature, full conversion into the undesired β-H migration product 25 was observed (entry 8). Similarly, the (salen)cobalt(II) catalyst 16 showed no catalytic activity even at room temperature (entry 9).

In our synthetic route, the cyclopropanation of allene (23) with diazopropanoate 4 in the presence of 1 mol% of the dirhodium catalyst Rh₂(η-R-TBPTTL₄)₄ (10) provided the enantio-merically enriched methylene cyclopropane (S)-24 on multi-gram scale. Ether aminolysis with the lithium salt of 26 gave the vinylogous imide 27 in 80% yield and 87:13 e.r. (Scheme 8). Deprotonation of 27 with NaHMDS in THF at −78 to −50 °C formed the corresponding sodium enolate, which was trapped with TBSCI to give the silyl enol ether intermediate 28. When heated at 95 °C in THF in the micro-

**Figure 2** Cyclopropanation catalysts

**Scheme 6** Preparation of chiral dirhodium catalyst 10

**Scheme 7** Preparation of chiral dirhodium catalyst 11
wave reactor, this diene underwent the intramolecular strain-promoted Diels–Alder (IMDAMC) reaction, and TBAF cleavage of the product silyl enol ether formed the desired trans-adduct 30 in 66% yield along with the cis-adduct 29 in 15% yield. These two diastereomers were readily separated chromatographically. Dehydrogenation of 30 under modified Diao–Stahl conditions 14 with Pd(TFA)$_2$ and DMSO in AcOH under an atmosphere of oxygen at 55 °C gave the corresponding enone 31 in 66% yield as a single regiosomer. Interestingly, dehydrogenation of the epimer 29 under these conditions provided the opposite enone regiosomer 32 stereospecifically in 56% yield. This complete switch in regioselectivity for the cis- and trans-diastereomers 29 and 30 parallels results obtained for the enolization of cis- and trans-2-decalones. 22 The configuration at the decalin ring junction governs the regioselectivity of enolization process due to torsional strain effects. The torsional strain that was proposed to govern the regiochemistry of enolization in cis- and trans-decalones has also been investigated in greater detail in relevant cis- and trans-octalins. 22b, 23

Enone 31 was obtained as a crystalline solid, and its enantiomeric ratio could be further enriched by recrystallization from 87:13 to yield product with >99% e.r. Chiral SFC analysis was used to evaluate each batch for enantiomeric purity.

For the completion of the total synthesis, stannane 34 was treated with n-BuLi at low temperature and converted into the corresponding lithium carbamion (Scheme 9). Addition of enone 31 to the reaction mixture delivered two diastereomeric allylic alcohols, which could be separated by chromatography on silica gel to give α-alcohol 35 and β-alcohol β-35 in 41% and 32% yield, respectively. The intramolecular Diels–Alder (IMDARF) reaction of α-35 (bearing a pseudo-equatorial hydroxy group) at 135 °C in a sealed tube was followed by spontaneous aromatization and cleavage of the Tempoc protecting group under the reaction conditions to form indole 36. The stereoisomeric alcohol β-35 was inert under these conditions, quite likely due to steric strain in the transition state that requires a pseudo-axial position of the substituent bearing the furan ring. Finally, lactam reduction led to (−)-cyclocaine in 34% yield over two steps from α-35. Overall, the synthesis of the natural enantiomer was accomplished in 8 steps and 4% yield. The specific rotation of the synthetic material was determined
to be +61.4 (c 0.2, CHCl₃), which was consistent with the literature value +63 (c 1, CHCl₃). Mass spectra, IR, ¹H, and ¹³C NMR data were also consistent with the previously reported data for the natural product as well as its enantiomer.⁴,¹¹

In contrast to the vast literature on lysergic acid derivatives, relatively little is known about the pharmaceutical potential of clavine ergot alkaloids.²b Lysergic acid derivatives, most notably lysergic acid diethylamide (LSD) have significant hallucinogenic properties that can interfere with their therapeutic potential. Most of these effects are thought to be mediated through agonist action at the 5-hydroxytryptamine receptor 2A, 5-HT₂A. In the tailwind of the rapidly expanding medical uses of cannabinoids, the mushroom metabolite psilocybin, and even LSD, are now moving to the forefront of clinical research on the management of mental health, anxiety, neurodegeneration, and substance-use disorders.²⁴ It would appear that more fundamental research on efficacy, tolerability, and safety of serotonergic psychedelics is highly warranted.

It is well known that binding of lysergic acid derivatives to brain membrane receptors is stereospecific, since L-LSD, the psychotropically inactive enantiomer of LSD, is ca. 1000 times weaker as a brain membrane receptor radioligand displacing agent,²⁶ and L-LSD as well as the other diastereomers, D-iso-lysergic acid diethylamide (iso-LSD) and l-iso-lysergic acid diethylamide (l-iso-LSD), show no psychic effects in humans up to a dose of 0.5 mg, which corresponds to a 20-fold increase over a still distinctly active D-LSD dose.²⁶ Having gained ready synthetic access to both natural (+)-cycloclavine and its unnatural enantiomer (–)-cycloclavine,¹¹ we were therefore interested to determine the receptor profiles of both compounds, and compare them to other serotonergic agents.

For an initial survey, we selected 13 pertinent CNS receptors and profiled both enantiomers at 10 mM concentration (Table 2). Compound binding was calculated as a percent inhibition of a radioactively labeled ligand specific for each target. As a group, the cycloclavines were more selective in this receptor panel than D-LSD,²⁷,²⁸ the bioactive LSD stereoisomer. D-LSD was active at the adrenergic µ₁ and histamine H₁ receptors (Table 2, entries 1 and 6), whereas both...
cycloclavines were moderately active at the opiate κ receptor (entry 10). Neither ergot chemotype showed significant activity at GABA_A, muscarinic M2 and M3, and nicotinic acetylcholine α4β2 receptors (entries 5, 7, 8, and 9). We were unable to find LSD data on orexin OX1, but cycloclavine did not perturb radioligand binding at this site at a 10 μM concentration (entry 11).

Significant differences between (+)- and (–)-cycloclavine revealed themselves in the dopamine D1, D2L, and D3 monoamine receptor family (Table 2, entries 2–4). In close analogy to D-LSD, natural (+)-cycloclavine maintained strong affinity to these receptors, which stimulate cognitive and motor functions. (–)-Cycloclavine showed comparatively moderate activity at the dopamine D3 receptor at 10 μM concentration, but fell below the threshold of 50% inhibition at 1 μM, whereas (+)-cycloclavine still maintained significant binding at this concentration (entry 4). A less prominent but still distinctive stereospecificity was observed at the serotonin 5-HT1A and 5-HT2A receptors (entries 12 and 13). Natural (+)-cycloclavine had very potent binding properties at both 10 and 1 μM, whereas (–)-cycloclavine tailed off at 1 μM. Serotonin receptors regulate a plethora of behavioral responses, from aggression, anxiety, appetite, to learning, memory, sleep, and even aging.25 D-LSD is one of the most potent agonists at 5-HT1A, and the affinity at the 5-HT2A, and possibly the 5-HT2C receptors versus the 5-HT1A receptor correlates with the mental effects of psychedelics in humans.30 In view of this interesting stereospecificity, and the significance of 5-HT receptors to human behavior, we decided to pursue additional studies on 5-HT subtypes (Table 3).

The purpose of our second generation functional assays on human 5-HT receptors was to determine effective concentrations EC50 or inhibitory constants (KI) for (+)-cycloclavine and (–)-cycloclavine. Cellular agonist effects were calculated as a percentage of a control response to a validated reference for each target, and cellular antagonist effect was calculated as a percentage of a control response to a validated reference for each target. In addition to D-LSD, we selected N,N-dimethyltryptamine (DMT) and psilocin as two relevant reference compounds.31,32 DMT is the only known endogenous N,N-dimethylated trace amine in mammals, and a prominent component in the sacramental tea ayahuasca.31 Its psychopharmacology has recently been compared to so-called ‘near-death experiences.’34 Psilocin is the pharmacologically active agent after ingestion of the prodrug psilocybin present in some species of psychedelic mushrooms. Psilocybin is currently clinically investigated as a treatment for anxiety and depression in cancer care, as well as for enhancement of cognitive flexibility and creativity.35

As suggested by the preliminary assays, (+)-cycloclavine provided considerably more potent at the 5-HT1A receptor than (–)-cycloclavine with an activation potency EC50 = 0.14 μM versus ~5 μM for (–)-cycloclavine (Table 3, entry 1). Both stereoisomers are poor activators at 5-HT2A, suggesting that hallucinogenic or strongly euphoric effects in humans might be limited in comparison to D-LSD, even though (+)-cycloclavine displays its most potent activation potential EC50 = 0.14 nM at 5-HT2C, a receptor that is thought to contribute to the observed mental effects of psychedelic drugs (entries 2 and 4). With the exception of DMT, which has only moderate potency, none of the tested agents activated 5-HT2A, a 5-HT receptor subtype that has been associated with cardiotoxicity. Overall, the 5-HT profile of (+)-cycloclavine closely mirrors that of psilocin, and to a lesser extent, that of DMT. It is substantially different from D-LSD, a property that we believe bodes well for future therapeutic investigations of this compound class.

The unusual activity on the opioid κ receptor, and the relative similarity to psilocin and DMT in the 5-HT panel inspired us to also evaluate the activity of cycloclavines in the sigma-1 assay, a receptor that was originally mischaracterized as an opioid receptor and has now been implicated in neuroinflammation and neuroprotection.36 DMT was identified as an endogenous sigma-1 receptor regulator.33,37 Surprisingly, while (+)-cycloclavine was inactive, the unnatural (–)-cycloclavine was determined to have a Ki = 8.3 μM for

the inhibition of the binding of the radiolabeled agonist haloperidol to sigma-1, and therefore found to be very similar to DMT (Kᵢ = 5.2 μM) (Table 3, entry 5). To the best of our knowledge, this is the first time that stereospecific binding of ergot alkaloids to a sigma receptor has been observed, and, accordingly, it is feasible to consider (−)-cycloclavine as a potential lead structure for sigma receptor modulator design.

In conclusion, we have successfully completed a total synthesis of natural (+)-cycloclavine, featuring an optimization of the catalyst for the asymmetric cyclopropanation of allene with an active ester diazopropanoate, a regiospecific Pd-catalyzed ketone dehydrogenation to the enone, and two intramolecular Diels–Alder reactions for indole/indoline annulations. Furthermore, we have characterized the binding effects of (+)- and (−)-cycloclavine against 16 CNS receptors, and discovered significant stereospecificity properties. (+)-Cycloclavine has at least 10-fold higher potency at the serotonin 5-HT₁C receptor than at any of the other tested receptors, making it one of the most selective tryptamines discovered to date. Furthermore, the receptor subtype profile of (+)-cycloclavine resembles that of the clinically validated mushroom metabolite psilocin more closely than the related psychedelics LSD and DMT. Finally, we determined that the unnatural (−)-cycloclavine has considerably lower affinities at all 5-HT receptors than (+)-cycloclavine, but is quite active at the sigma-1 receptor, a property that it shares with the endogenous sigma-1 ligand DMT. We suggest that these results, in combination with the excellent synthetic tractability of the cycloclavine scaffold, encourage future research on the medicinal chemistry of clavine alkaloids.

All glassware were dried in an oven at 140 °C for at least 2 h prior to use. All air and moisture-sensitive reactions were performed under a dry N₂ atmosphere. Reactions carried out at 0 °C employed an ice bath. THF and Et₂O were distilled over Na/benzophenone ketyl; Et₃N, CH₂Cl₂, and toluene were distilled from CaH₂. All other materials were obtained from commercial sources and used as received. Microwave reactions were performed using a Biotage Initiator or an Anton Paar Monowave 300 reactor in glass microwave vials (cap sealed) with continuous magnetic stirring and internal rubber thermometer and/or external infrared surface temperature sensor. IR spectra were obtained from neat solids or oils on ATR FT-IR spectrophotometers. Melting points were determined in open capillary tubes and are uncorrected. High-resolution mass spectra were obtained on a Q-TOF MS or a Thermo Scientific Exactive Orbitrap LC-MS. 1H and 13C NMR spectra were obtained at 300, 400, 500, 600, or 700 MHz NMR in CDCl₃, unless otherwise specified. 13C NMR spectra were obtained at 100, 125, or 150 MHz with proton-decoupling. Chemical shifts (δ) are reported in parts per million with the residual solvent peak used as an internal standard: 1H/13C (Solvent) δ = 7.26/77.16 (CDCl₃); 7.16/128.06 (CD₂Cl₂), 5.32/54.00 (CDCl₃), and 2.08/20.43 (toluene-d₈) and are tabulated as follows: chemical shift, multiplicity (standard abbreviations), and coupling constant(s), number of protons. Reactions were monitored by TLC analysis (pre-coated silica gel 60 F254 plates, 250 μm layer thickness) and visualization was accomplished with a KMnO₄ solution (1.50 g of KMnO₄, 10 g of K₂CO₃, and 1.25 mL of 10% NaOH in 200 mL of H₂O), when needed. Flash chromatography was performed using SiO₂ (40–63 μm). Specific rotations were measured on a polarimeter equipped with a sodium lamp. Pentfluoro-phenyl 2-diazopropanoate (4)¹¹ and stannane 34¹¹ were prepared as reported previously.

N-Tetrabromophthaloyl-(R)-tart-leucine
An oven-dried flask topped with a Dean–Stark apparatus and condenser was charged sequentially with (R)-tart-leucine [(R)-18; 0.500 g, 3.77 mmol], tetrabromophthalic anhydride (17; 1.79 g, 3.77 mmol), anhyd toluene (10 mL), and NEt₃ (0.0536 mL, 0.377 mmol). The resulting heterogeneous mixture was heated at reflux while the solvent was removed at a rate of ca. 1 mL/h. The solution was cooled to r.t. and treated with aq 5% HCl (6 mL) and EtoAc (15 mL). The aqueous layer was extracted with EtoAc (6 mL) and the combined organic layers were dried (Na₂SO₄) and concentrated to give N-tetrabromophthaloyl-(R)-tart-leucine as a white solid; yield: 2.11 g (97%); [α]D²⁰ +22.3 (c 0.40, EtOH).

The experimental data were consistent with the literature-reported data for the enantiomer.¹⁸

Dirhodium(II) Tetrakis[N-tetrabromophthaloyl-(R)-tart-leucinate] [Rh₂(R-TBPTTL)₄, 10] An oven dried flask topped with a Dean–Stark apparatus and condenser was charged with Rh₂OAc₃ (0.130 g, 0.294 mmol), N-tetrabromophthaloyl-(R)-tart-leucine (0.933 g, 1.62 mmol), and a mixture of chlorobenzene and MeCN (9:1, 13 mL). The resulting dark purple solution was heated at reflux while the solvent was removed at a rate of ca. 1 mL/h over 5 h, during which time the solution turned emerald green. After 5 h, the reaction mixture was cooled to r.t. and treated sequentially with toluene (40 mL) and satu. aq NaHCO₃ (40 mL). The organic layer was washed with NaHCO₃ (40 mL), brine (40 mL), filtered, and dried (Na₂SO₄) to provide 10 (0.555 g, 75%) as a green solid, which was used directly without further purification.

¹H NMR (300 MHz, acetone-d₆): δ = 6.68 (s, 1 H), 1.19 (s, 9 H).

The experimental data were consistent with the literature-reported data for the enantiomer.³⁸

4,7-Diphenyl-3a,4,7,7a-tetrahydroisobenzofuran-1,3-dione
A clear, yellow solution of butadiene 19 (2.0 g, 9.6 mmol) and maleic anhydride 20 (1.1 g, 11 mmol) in xylenes (25 mL) was heated at 140 °C for 16 h. After this time, the reaction was cooled to 0 °C and the resulting precipitate was filtered to afford the Diels–Alder adduct as a white solid; yield: 2.29 g (78%).

¹H NMR (500 MHz, CDCl₃): δ = 7.43 (app t, J = 7.3 Hz, 4 H), 7.39–7.36 (m, 6 H), 6.56 (s, 2 H), 3.84 (d, J = 4.0 Hz, 2 H), 3.74 (dd, J = 4.5, 2.0 Hz, 2 H).

The experimental data were consistent with the literature-reported data for the enantiomer.³⁸

4,7-Diphenylisobenzofuran-1,3-dione (21)
A red solution of 4,7-diphenyl-3a,4,7,7a-tetrahydroisobenzofuran-1,3-dione (1.0 g, 3.3 mmol) and DDQ (1.5 g, 6.6 mmol) in toluene (10 mL) was heated at 110 °C for 17 h. The reaction mixture was concen-
treated and filtered, and the solid was washed with EtOH to provide crude 21 (0.832 g, 84%) as a light pink solid that was used without further purification.

1H NMR (300 MHz, CDCl3): δ = 7.85 (s, 2 H), 7.61–7.57 (m, 4 H), 7.54–7.51 (m, 6 H).

The experimental data were consistent with the literature-reported data.39

(5)-2-(1,3-Dioxo-4,7-diphenylisoindolin-2-yl)-3,3-dimethylbutanoic acid (22)

An oven-dried microwave vial was charged sequentially with 4,7-dinonic Acid (22) (0.300 g, 1.00 mmol), (S)-tert-leucine (0.199 g, 1.50 mmol), and NEt3 (0.0283 mL, 0.200 mmol), and the resulting heterogeneous brown solution was heated at reflux for 19 h. The solution was cooled to r.t., and extracted with aq 5% HCl and EtOAc. The aqueous layer was back-extracted with EtOAc (3 ×), and the resulting heterogeneous brown solution was heated at reflux for 280–282.9 °C (dec.).

13C NMR (100 MHz, CDCl3): δ = 132.3 (8 C), 129.9 (8 C), 128.2 (16 C), 127.8 (16 C), 60.7 (EtOAc), 60.6 (4 C), 35.6 (4 C), 28.2 (12 C), 21.2 (EtOAc), 14.3 (EtOAc).

Pentafluorophenyl (R)-1-Methyl-2-methylene cyclopropane-1-carboxylate (24)

An oven-dried three-necked flask was charged with the respective catalyst (0.0056 mmol) and hexanes or CH2Cl2 (2.8 mL), and the resulting green solution was cooled to −78 °C and treated dropwise with an excess of condensed gaseous allene (23; ca. 14 mmol). The reaction mixture was then treated with a solution of pentafluorophenyl 2-diazopropanoate (4; 0.56 mmol) in hexanes or CH2Cl2 (1.7 mL) via syringe pump at a rate of 1 mL/h. After the addition was complete, the mixture was allowed to warm to r.t. The solution was concentrated under reduced pressure and the resulting residue was purified by chromatography on SiO2 (0–2% Et2O/hexanes) to provide methylencyclopropane (R)-24.

1H NMR (400 MHz, CD2Cl2): δ = 5.64 (t, J = 2.8 Hz, 1 H), 5.56 (t, J = 2.2 Hz, 1 H), 2.30 (dt, J = 9.2, 2.5 Hz, 1 H), 1.63 (dt, J = 9.2, 2.4 Hz, 1 H), 1.51 (s, 3 H).

Pentafluorophenyl (S)-1-Methyl-2-methylene cyclopropane-1-carboxylate (S)-24 (Table 1, entry 3)

An oven-dried three-necked flask fitted with a N2 inlet, a dry-ice condenser, and a septum was charged with Rh2(OAc)4 (0.016 g, 0.036 mmol), and chlorobenzene (0.5 mL), and the mixture was allowed to stir at –78 °C for 1 h before warming to r.t. The solution was concentrated, and a septum was charged with Rh2(OAc)4 (0.0056 mmol) and hexanes or CH2Cl2 (2.8 mL). The resulting solution was then treated with a solution of pentafluorophenyl 2-diazopropanoate (4; 0.56 mmol) in hexanes or CH2Cl2 (1.7 mL) via syringe pump at a rate of 1 mL/h. After the addition was complete, the mixture was allowed to warm to r.t. The solution was concentrated under reduced pressure and the resulting residue was purified by chromatography on SiO2 (0–2% Et2O/hexanes) to afford methylencyclopropane (S)-24 as a clear and pale yellow oil; yield: 5.41 g (86%); [α]20^23 +2.8 (c 7.6, CHCl3).
2.29 (s, 3 H), 1.80 (dt, J = 13.5 Hz, 1 H), 5.71 (app t, J = 9.8, 2.4 Hz, 1 H), 1.51 (s, 3 H).
HRMS (ESI+): m/z calcld for C₂₂H₂₈F₂O₂ (M + H)⁺: 379.0439; found: 379.0450.
All other experimental data were consistent with the reported data for the enantiomer.11

(5E)-N,1-Dimethyl-2-methylene-N-(3-oxobut-1-en-1-yl)cyclopropane-1-carboxamide ([S]-27)
An oven-dried round bottomed flask was charged with vinylogous amide 26 (2.77 g, 27.9 mmol) and evacuated and backfilled with N₂ (3 ×). Distilled THF (93 mL) was added and the resulting solution was cooled to –78 °C and treated dropwise with n-BuLi (11.7 mL, 2.5 M solution in hexanes, 29.3 mmol). The mixture was stirred for 5 min at –78 °C, then treated dropwise with a solution of pentfluoromethyl (S)-1-methyl-2-methylene-cyclopropane-1-carboxylate ([S]-24; 8.15 g, 29.3 mmol) in THF (15 mL). The reaction mixture was treated with DMAP (0.0341 g, 0.279 mmol) and stirred for 10 min at –78 °C. The cold bath was removed and the solution was allowed to warm to r.t., and quenched with sat. aq NaHCO₃ and EtOAc. The aqueous layer was washed with MTBE (2 ×) and the combined organic layers were dried (Na₂SO₄) and concentrated. The crude product was purified by chromatography on SiO₂ (10–15% EtOAc/hexanes) to afford [[(S)-27]; yield: 4.30 g (80%); e.r.: 87:13 by SFC analysis] as a clear and pale yellow oil; [α]D¹⁰ = –243.2 (c 2.24, CHCl₃).

1H NMR (500 MHz, CDCl₃): δ = 8.37 (d, J = 14.0 Hz, 1 H), 5.73 (d, J = 13.5 Hz, 1 H), 5.71 (app t, J = 2.8 Hz, 1 H), 5.53 (s, 1 H), 3.15 (s, 3 H), 2.29 (s, 3 H), 1.80 (dt, J = 9.8, 2.4 Hz, 1 H), 1.50 (s, 3 H), 1.33 (dt, J = 9.7, 2.4 Hz, 1 H).

HRMS (ESI+): m/z calcld for C₁₁H₁₆NO₂ (M + H)⁺: 194.1176; found: 194.1175.

(1α,3α,7αR)-1a,3-Dimethylhexahydro-2H-cyclopenta[c]indole-2,5(3H)-dione (30) and (1α,3α,7αR)-1a,3-Dimethylhexahydro-2H-cyclopenta[c]indole-2,5(3H)-dione (29)
An oven-dried flask was charged with NaHMDS (2.50 g, 12.9 mmol) and anhyd THF (150 mL) under an atmosphere of N₂. The resulting clear and colorless solution was stirred for 15 min at r.t., then cooled to –78 °C, and stirred for a further 15 min at this temperature prior to treatment with a solution of 27 (2.75 g, 14.2 mmol) in THF (20 mL) slowly at a rate of ca. 4 mL/h, maintaining the temperature of the acetone/dry ice bath below –50 °C. During the slow addition of the amine, the solution changed color from clear and pale yellow to clear and orange. The resulting clear, orange solution was allowed to warm to –78 °C, and stirred for a further 15 min at –78 °C before the cold bath was removed, and the solution allowed to reach r.t.

1H NMR analysis of an aliquot (CDCl₃) indicated conversion into enol ether 28.

1H NMR (300 MHz, CDCl₃): δ = 7.65 (d, J = 13.5 Hz, 1 H), 5.67 (app s, 1 H), 5.52 (d, J = 13.8 Hz, 1 H), 5.45 (app s, 1 H), 4.23 (s, 2 H), 3.13 (br s, 3 H), 1.73 (dt, J = 9.6, 2.1 Hz, 1 H), 1.47 (s, 3 H), 1.25 (dt, J = 9.4, 2.2 Hz, 1 H), 1.00 (s, 3 H), 0.25 (s, 3 H), 0.24 (s, 3 H).

The mixture was concentrated and directly subjected without purification to the next reaction. A solution of crude amide 28 (assumed 3.98 g, 12.9 mmol) in THF (28 mL, 3.5 mL × 8 batches) was heated under microwave irradiation at 95 °C for 30 min, then concentrated to deliver the crude Diels–Alder adducts (assumed 3.98 g, 12.9 mmol) as an orange oil that was used directly in the next conversion. The crude enol ether adducts (assumed 3.98 g, 12.9 mmol) were immediately dissolved in THF (130 mL), treated dropwise with TBAF (12.9 mL, 1 M solution in THF, 12.9 mmol) and stirred at r.t. for 30 min. The reaction mixture was filtered through a pad of Florisil (washed with EtOAc) and concentrated. The resulting residue was purified by chromatography on SiO₂ (20% EtOAc/hexanes to elute recovered starting material, then 50–70% EtOAc/hexanes to elute the trans-diastereomer 30, then 90–100% EtOAc/hexanes to elute the cis-diastereomer 29) to provide trans-ketone 30 as a pale yellow solid (1.64 g, 66%) and cis-ketone 29 as a yellow oil (0.371 g, 15%).

All other experimental data were consistent with the reported data for the enantiomer.11

29
[a]D¹⁰ = +11.0 (c 0.15 CHCl₃).

1H NMR (300 MHz, CDCl₃): δ = 3.73 (app t, J = 6.5 Hz, 1 H), 2.84 (dd, J = 15.0, 6.0 Hz, 1 H), 2.72 (s, 3 H), 2.53–2.25 (m, 4 H), 1.83 (dt, J = 14.2, 5.2 Hz, 1 H), 1.34 (s, 3 H), 0.93 (d, J = 4.5 Hz, 1 H), 0.84 (d, J = 4.5 Hz, 1 H).

HRMS (ESI+): m/z calcld for C₁₁H₁₅NO (M + H)⁺: 194.1176; found: 194.1178.

Enantiomeric Enrichment by Recrystallization of Enone 31; Typical Procedure
Enone 31 (0.110 g, 0.573 mmol) was dissolved in boiling MTBE (9.5 mL) and 1,2-dichloroethane (0.4 mL) and the solution was allowed to cool to r.t., and kept overnight at –20 °C. The mother liquor was removed via pipette transfer and the white needle-shaped crystals were washed with MTBE (2 ×) and placed under vacuum to remove trace solvents. The first recrystallization provided compound of 99.5:0.5 e.r. by chiral SFC analysis; a 95.4:4.6 e.r. was achieved in the second recrystallization, and the third recrystallization led to 98:2 e.r. to deliver a combined yield of enone 31 (0.0654 g, 60%, 69% of theoretical maximum) as a white crystalline solid. Only combined samples with e.r. >97.5:2.5 were carried on in the subsequent reaction; [α]D¹⁰ = +111.1 (c 0.484, CHCl₃).
An oven-dried 3-necked 25 mL flask fitted with two stoppers and N₂ using a liquid N₂/Et₂O bath, and treated with a solution of enone was maintained between –67.4 and –74.5 °C, then cooled to –93.1 °C. The resulting clear, yellow solution was stirred for 15 min while the internal temperature below –50 °C. The aqueous layer was extracted with EtOAc and quenched with aq 2 M NH₄Cl, maintaining the internal temperature at 55 °C under an atmosphere of O₂ (balloon) for 20 h then added to each eluent) to deliver (+)-cycloclavine as a white solid; yield: 0.029 g (56%).
