Should We Adopt a Standard International Normalized Ratio Range of 2.0 to 3.0 for Asian Patients with Atrial Fibrillation? An Appeal for Evidence-Based Management, Not Eminence-Based Recommendations

The prevalence of atrial fibrillation (AF) and AF-related stroke are increased in Asian countries in recent years,1,2 and stroke prevention with oral anticoagulants (OACs) is the cornerstone for the managements of AF.3,4 Although non-vitamin K antagonist OACs (NOACs) were more and more commonly prescribed, warfarin was still responsible for around 27% of prescriptions of OACs for newly diagnosed AF patients in year 2015 in Taiwan.5

When using warfarin, we have to think beyond simply writing a prescription for it. Good treatment quality assessed by international normalized ratio (INR) and time in therapeutic range (TTR) is important for warfarin therapy. Some data suggest that the risk of warfarin-related intracranial hemorrhage (ICH) may be different between different ethnic groups. In the subanalysis of ENGAGE AF-TIMI 48 trial, patients of Asian races were associated with a higher adjusted risk of ICH (adjusted hazard ratio: 1.71; p = 0.03) compared with non-Asians despite a lower INR range.6 Actually, whether there should be a lower INR range for Asian AF patients remains as a debate for many years mainly due to the lacking of high-quality data of randomized trials. Indeed, some studies have tried to focus on stroke and bleeding in Asian populations, attempting to define thromboembolic and bleeding issues in this ethnic group.7–9 Nevertheless, an “Asian” group is very broad—and South Asians from the Indian subcontinent are very different from oriental subjects from East Asia or Central Asia, whether biologically or culturally.

The recommendations of different Asian guidelines on the optimal INR ranges for AF patients treated with warfarin are summarized in Table 1. The Taiwan Heart Rhythm Society, China Society of Pacing and Electrophysiology/Chinese Society of Arrhythmia, and Korean Heart Rhythm Society recommend 2 to 3 as an optimal INR range,10–12 which was similar to the majority of western guidelines. However, Japanese, Indian, and Chinese Geriatric Society guidelines recommend a lower INR range for elderly patients.13–15 The Japan Circulation Society (JCS) recommends an INR range of 1.6 to 2.6 for AF patients aged ≥70 years,13 while the Chinese Geriatric Society and Indian consensus guidance suggest an INR level of 2.0 (range = 1.6–2.5) for patients aged >75 years.14,15 Regarding the quality of warfarin use, the Taiwan Heart Rhythm Society, China Society of Pacing and Electrophysiology/Chinese Society of Arrhythmia, and Korean Heart Rhythm Society recommend a TTR >65%, while the JCS recommends a TTR above 60%. These discrepancies of recommended INR range between different Asian guidelines reflect the uncertainty regarding this important issue, given the lack of high-quality studies.

In this issue of Thrombosis and Haemostasis, Pandey et al present a meta-analysis of 79 randomized controlled trials, where lower INR targets were associated with increased thromboembolism, decreased major bleeding, and similar mortality compared with standard INR ranges.16 In a subgroup analysis of only East Asian trials, lower INR target ranges were associated with higher rates of thromboembolism. The authors concluded that an INR range of 2 to 3 should remain the
standard for prophylaxis of thromboembolism in AF, including in East Asians, who were thought to derive less harm from lower INR targets. This study nicely provided some important data regarding the “optimal” INR range for Asian AF patients. However, the clinical outcomes were compared between patients with an INR range of 1.5 to 2.0 and 2.0 to 3.0, and therefore, whether a lower INR within the standard range (2.0–2.5), could offer a good balance between ischemic and bleeding events remains unknown although this would pose more challenges to get a high TTR in that narrow range.

In a recent paper by McDowell et al, data on warfarin-treated patients (n = 21,883) from three clinical trials (RE-LY, ARISTOTLE, and ENGAGE AF-TIMI 48) were pooled. The event rates of ischemic stroke, ICH and all-cause mortality of patients in different INR strata are shown in Fig. 1. An INR range between 2.0 and 2.5 appeared to offer a good balance between ischemic and bleeding events. The optimal therapeutic range of INR in the use of warfarin has not been fully established in Asians, although an INR 2.0–3.0 is recommended as the optimal therapeutic range, with attention on the average TTR; ideally >65%.

</table>

Abbreviations: INR, international normalized ratio; TTR, time in therapeutic range.

**Fig. 1** Estimated risks of ischemic stroke, ICH and mortality among AF patients receiving warfarin in different INR ranges. An INR range between 2.0 and 2.5 appeared to offer a good balance between ischemic stroke and ICH, which was also associated with the lowest rate of all-cause death. The data used in the figure were from the paper by McDowell et al published in Pharmacotherapy 2018. AF, atrial fibrillation; ICH, intracranial hemorrhage; INR, international normalized ratio.
between ischemic stroke and ICH, which was also associated with the lowest rate of all-cause death. Although the annual stroke rate slightly increased from 0.47% for an INR 2.5 to 3.0 to 0.54% for an INR 2.0 to 2.5, the risk of ICH decreased from 0.69 to 0.52%/year which was in favor of an INR range of 2.0 to 2.5, considering the overall net clinical benefits. Even data specific for Asian AF patients were not reported, this large-scale pooled analysis of high-quality data from clinical trials might imply that an INR range of 2.0 to 2.5 may be more appropriate than 2.5 to 3.0 for Asian patients who were at a high risk of ICH.

Overall, this study by Pandey et al nicely provides some unique data, but more high-quality studies, especially the prospective and randomized ones, are necessary to properly answer the optimal INR range for Asian AF patients. For now, we strongly recommend evidence-based management, with the strongest data currently for INR 2.0 to 3.0 and TTR ideally >65% (or even 70%). Evidence-based management should drive our clinical practice, not eminence or VIP-based opinion.
