Abstract

Across the globe, computed tomography is the most widely used imaging modality mentioned in the published literature on the recent COVID-19 pandemic. However, in terms of availability, ease of use, and sanitization of the equipment; chest radiograph is a much more feasible option. However, interpretation of radiographs needs expertise to achieve appropriate diagnostic accuracy. This article will discuss its current role in diagnosis and severity assessment, as well as a systematic approach toward interpretation.

Keywords

► CXR
► radiograph
► COVID-19
► radiology

Introduction

The recent COVID-19 pandemic has initiated many practice-changing trends in modern medicine. On the imaging front, this disease has been extensively evaluated using computed tomography (CT) scans and less frequently, using chest radiographs. In this article, we shall discuss the role of chest X-ray (CXR) in the current COVID-19 pandemic, and provide detailed reporting about it in a systematic manner.

CT Scan versus CXR

While the superior diagnostic accuracy of CT in the detection and quantification of changes in lung parenchymal pathology is not debatable, there are numerous advantages of using CXR in the setting of the current pandemic. The obvious advantages of CXR includes its low-cost and availability. Also, portable units can be deployed in COVID-19 wards, intensive care units (ICUs) and COVID screening areas within the emergency rooms (ERs). Even more important in the context of the highly contagious organism is the fact that sanitization/disinfection procedures for portable X-ray units is far less cumbersome than those for CT scanners. Hence, the use of X-rays is associated with less risk of cross-infection compared with CT scans.¹ As the number of patients affected by this pandemic grows, use of CXR as the primary imaging tool, with CT as a problem solving tool, seems an effective strategy.

For these reasons, while in the initial weeks of the pandemic in mainland China, the emphasis of imaging in COVID-19 pneumonia was on the use of CT scans, there has been an increasing reliance on CXRs across the world recently.²,³ Current evidence (based on published literature) on use of CXR in COVID pneumonia is listed in ►Table 1.

Role of CXR

The role of CXR in various scenarios is as follows:

COVID-19 Positive Patient (RT-PCR Positive)

• A dedicated portable CXR unit should be placed in the COVID ward/ICU and bedside CXRs performed.
• Personal protection of radiographers and sanitization of equipment should be performed as per society/institutional guidelines/standard operating protocols (SOPs)²,³
• Asymptomatic RT-PCR positive patients need not get CXR done.
• In symptomatic patients, periodic CXRs should be performed based on patient’s clinical status. Daily CXRs are not warranted.
COVID-19 Suspects

CXRs are advocated in all patients presenting with SARI (severe acute respiratory infection). In influenza-like illness (ILI), decision can be made on case-to-case basis.

CXR should be performed if any two of the following are present:
- Fever (without any apparent nonrespiratory cause).
- Shortness of breath.
- Immunocompromised host.
- Hypoxia (room air SpO2 < or equal to 94%).
- Respiratory rate >/= 20/ minute.

CXR Findings

Radiographic Patterns

Based on published literature and institutional experience, we have observed the following CXR patterns in COVID-19 pneumonia. Several radiographic patterns of COVID pneumonia have been described, several of which are considered classical signs of the infection.

Pattern 1: Peripheral Airspace Opacities

This is a classical pattern of COVID-19 pneumonia, wherein airspace opacities are distributed along the periphery of the

</table>
lung (►Fig. 1A). These opacities do not necessarily show a lower lobe predominance; in our experience, although there is, in fact, a relative sparing of the lung apices and costophrenic (CP) angles. This appearance is very similar to the “reverse batwing” appearance seen in chronic eosinophilic pneumonia or organizing pneumonia.

**Pattern 2: Bilateral Lower Zones Consolidation/Ground Glass Opacity**
This is the most frequently reported pattern (►Fig. 1B) in COVID-19 pneumonia. Compared with CT, ground glass opacity (GGO) can be difficult to appreciate on CXR, and hence the importance of viewing the CXR in optimal conditions. If superimposed septal thickening develops, GGO becomes easier to detect on CXR.

**Pattern 3: Peribronchial Consolidation**
Another pattern which has been reported on CT and observed by the authors on CXR is the peribronchial distribution of consolidation (►Fig. 1C), wherein dominant findings are present in the lower or midzones on both sides.

**Pattern 4: Multifocal Airspace Opacities/Consolidation/GGO**
This appearance is similar to pattern 2, except that the opacities do not show the bilateral, lower lobe distribution (►Fig. 1D). This appearance is frequently encountered in viral pneumonia; unlike unilobar consolidation, which is more frequent in bacterial community-acquired pneumonia (CAP). The presence of areas of breakdown suggests a bacterial etiology.

**Pattern 5: Large Nodule or “Mass-Like” Opacities (Ball Pattern)**
Large nodules/localized rounded consolidation has been reported as an uncommon/rare finding in a single case.11 We have, however, encountered this pattern in several COVID-19 pneumonia patients, which we refer to as “ball-pattern” (►Fig. 1E). These lesions do not always show a lower lobe predilection. The large nodule may be a solitary lesion or be present in conjunction with other patterns.

**Pattern 6: Diffuse Mid- and Lower Zones Consolidation/Airspace Opacities**
This pattern is seen in more severe forms of the disease, and corresponds to a clinical picture of acute respiratory distress syndrome (ARDS) (►Fig. 1F). Once these changes develop, the appearance is nonspecific and etiology has to be surmised on the current pandemic background, as this pattern can be seen with several inflammatory/infectious/multisystem processes.

**Fig. 1 (A-F).** CXR patterns of COVID-19 pneumonia. (A) Pattern 1: Peripheral reverse bat-wing (arrows) (B) Pattern 2: Lower and midzones GGO/consolidation (asterisk) (C) Pattern 3: Peribronchial consolidation (arrows) (D) Pattern 4: Multifocal nonspecific distribution (E) Pattern 5: Nodular/ mass-like (asterisk) (F) Pattern 6: ARDS. ARDS, acute respiratory distress syndrome; CXR, chest X-ray.
Pattern 7: Uncommon/Rare Patterns
Some additional rare lung changes include cavitation, and upper and middle lobe partial collapse, which is likely due to mucus plugs.

It should also be kept in mind that in a given patient more than one pattern can coexist.

Complications
Infrequent complications include pleural effusion, pneumothorax, pneumomediastinum, and subcutaneous emphysema. Air leaks are rare, as cavitation is rarely encountered in COVID-19 pneumonia, and are more likely to be seen as a complication of barotrauma following ventilation.

CXR Reporting
The labeling of a CXR in four different categories (normal, classic/probable, indeterminate, or non-COVID) should be adopted to convey a risk-stratified imaging information to the physician. Although there is no evidence on CXR for the categorization, this can be adopted as an extrapolation of CT-based risk stratification systems available with various society guidelines. In our institute, we adopt the following criteria (adapted from reference 13):

Normal: CXR normal; COVID-19 not excluded.
Classic/probable COVID-19: Lower lobe predominant and peripheral predominant; multiple, bilateral, areas of GGOs (Fig. 2).
Indeterminate: Does not fit into classic/non-COVID pattern (Fig. 3).
Non-COVID pattern: Pneumothorax, lobar consolidation, pleural effusion, and pulmonary edema (Fig. 4).

Sensitivity OF CXR
The reported sensitivity of CXR in diagnosis of COVID-19 ranges from 33.3 to 69% (Table 1). This sensitivity is lower than that of CT scans (up to 98%), and that of initial RT-PCR. It has, however, been shown that CXR may be abnormal in some patients (reported in 9% cases by Wong et al), even when initial RT-PCR is negative. Hence, in view of the various advantages of CXR listed earlier, it is likely to be a useful tool during the pandemic.

A critical point while reporting the CXR is that it should be viewed in optimal viewing conditions, preferably on a picture archiving and communication system (PACS) with appropriate monitor by a qualified radiologist. Interpretation of the same in suboptimal conditions or by non-expert personnel will result in missing of subtle findings and misinterpretation and hence lower diagnostic accuracy. Also, non-COVID diagnosis should not be labeled as COVID-19 related due to the pandemic. It is hence suggested that understandably the CXR will be interpreted in the ER by the treating physician; however, subsequently an additional formal radiology report should always be sought and consulted.

CXR Scoring System
Recently, CXR is being used more frequently than CT to monitor the “day-to-day” progression of the pulmonary involvement of SARS-CoV-2. This was first emphasized in an Italian study, and its role emphasized in the setting of a rising number of SARS CoV-2 cases and resultant ICU admissions. If CXR is to be used as a tool for monitoring disease progression, it is important to express the extent of involvement quantitatively. To the best of our knowledge, only two CXR scoring systems...
have been described for COVID-19 pneumonia in English literature so far, and we are employing a third scoring system at our institute, which is under validation.

The first scoring system employed by a S. Korea based group considers the entire lung together, and it is mainly based on the expected pattern of progression of the pneumonia (►Table 2). In the second scoring system employed and validated by Italian investigators,\(^{16}\) each lung was divided into three zones, with the maximum score for each zone being 3 and the total score being 18. The description within the zones was based predominantly on the pattern within the zone, whether interstitial, alveolar or combined, with alveolar opacities representing more severe disease.

In the scoring system employed at our institute, the lungs are divided into three zones each (similar to Borghes et al), but the score is based on the percentage of lung involved within the zone rather than the pattern (►Figs. 5 and 6). The maximum score for each zone is 4 and

                                                               | On hospitalized patients with acute respiratory infections                                    | No                 |
| Borghesi et al\(^6\) | Both lungs divided in three zones each (upper, middle, lower). Each zone is given a separate score 0–3 (max score: 18) 0: normal 1: interstitial infiltrates 2: Mixed interstitial and alveolar infiltrates (predominantly interstitial) 3: Mixed interstitial and alveolar infiltrates (predominantly alveolar) | No prior study                                                                                           | Yes                |
| Our institute   | Each lung divided into three zones. Within each zone, a score 0–4 is given. (max score: 24) 0: normal 1: 1–25% of area involved 2: up to 50% of area involved 3: up to 75% of area involved 4: >75% of area involved | No prior study                                                                                           | Under validation   |

Abbreviation: CXR, chest X-ray.
hence the total score is 24. This score is currently under validation at our institute.

**CXR and Disease Monitoring**

Worsening of radiographic changes are generally concordant with clinical imaging. The peak CXR changes have been reported between day 10 to 12(from infection onset). While some studies have shown that radiological and virological recovery parallel each other, discordant timelines have been demonstrated by others.\(^4\)

**Structured Reporting**

The authors propose the use of a structured reporting format while reporting CXR in suspected/proven COVID-19 cases. Whereas CO-RADS, a standardized reporting tool in CT of COVID-19 patients,\(^18\) is already in use, similar tools in CXR are not widely used. Various societies have proposed structured reporting templates for CXR.\(^4,13\) \(\text{Fig. 7}\) describes the structured reporting format used at our institute which was proposed by Indian College of Radiology and Imaging.\(^4\)

**Conclusion**

Hence, CXR is a valuable tool in better management of patients during the COVID-19 pandemic. Despite its lower sensitivity compared with CT scans, its myriad inherent advantages make it indispensable. Further addition of chest
ultrasound to the CXR in ICU settings will immensely reduce the need for CT scans.
