Abstract

Introduction This study aimed to evaluate the toxicity and the antiangiogenic activity of *Murraya koenigii* leaf extracts in zebrafish.

Materials and Methods Crude aqueous and ethanol extracts of *M. koenigii* leaves were obtained following a standard solvent-based extraction method. The toxicity of these extracts on zebrafish embryonic development was determined and the LC_{50} values were calculated. Finally, the antiangiogenic activity of the *M. koenigii* leaf extracts was evaluated in a transgenic zebrafish (*Tg* [*fli1*: GFP]) that express GFP under the control of *fli1*, a transcription factor involved in vasculogenesis.

Keywords

- ► Murraya koenigii leaves
- ► embryo
- ► toxicity
- ► zebrafish
- antiangiogenic activity
- ► Tg (fli1: GFP)

the control of *fli1*, a transcription factor involved in vasculogenesis. **Results** The LC₅₀ value of the aqueous extract of *M. koenigii* leaves was much larger (2,450 ppm) compared with that of ethanol extract (9.85 ppm), suggesting a lower toxicity of the aqueous extract. The antiangiogenic activity was evident only in aqueous extract, with significant effects in formation of intersegmental vessels and subintestinal veins in treated *Tg* (*fli1*: GFP) zebrafish embryos.

Conclusion This study demonstrated the biological activity of *M. koenigii* leaf extracts as angiogenesis suppressor, suggesting its therapeutic potential as an angiogenesis inhibitor. Identification of active components from natural sources with potent antiangiogenic activity could lead to the development of anticancer agents.

Introduction

The increasing demand for chemical diversity in screening programs leads to the identification of therapeutic drugs from natural products, particularly from edible plants. According to the World Health Organization, more than 80% of the world's population rely on traditional medicine for their primary health care needs.^{1,2} The application of medicinal plants in traditional medical treatments is significant in both developing and industrialized countries.^{3,4}

Murraya koenigii (curry tree), a small aromatic plant belonging to the family Rutaceae, is native to India and is used in the Ayurvedic system of medicine.⁵ Leaves, roots, and bark of this plant have been demonstrated as rich sources of carbazole alkaloids with potent biological activities.⁶ Some of the pharmacological effects such as antioxidant, antidiabetic, anti-inflammatory, antitumor, anticancer, and neuroprotective activities have been reported for *M. koenigii.*^{2.7.8} The leaves are rich source of polyphenols, which can inhibit the proteolytic activity of the cancer cell and cause cell death.

Angiogenesis is a complex process involved in the development of new blood vessels from preexisting vasculature, mainly for endothelial cell proliferation, organization, and migration.^{9,10} It plays an important role in tumor progression by stimulating blood vessel growth from nearby capillaries as a prelude to metastasis. Tumor growth and metastasis in cancer states have been reported as angiogenesis dependent.¹¹ Persistent unregulated angiogenesis is a hallmark of cancer.¹² Therefore, blocking angiogenesis is considered as an encouraging strategy in cancer therapy.

In recent years, zebrafish (*Danio rerio*) has gained tremendous popularity as an in vivo model in biomedical research due to its several inherent properties. Zebrafish has high fecundity, the embryos are optically transparent, and it has short generation time. The zebrafish is amenable to high throughput screening in drug discovery and it is inexpensive to maintain. The ease of genetic manipulation and the availability of many transgenic lines where the blood vessels are tagged with fluorescent proteins allowing real-time visualization of the process of vasculogenesis make it an ideal system for screening antiangiogenic compounds.^{13,14}

In this study, we have obtained crude extracts of *M. koenigii* leaves using two different solvents and determined the toxicity of these compounds. Further, we investigated the antiangiogenic activities of these extracts in transgenic zebrafish embryos (*Tg* [*fli1*: GFP]) that expressed GFP under the control of *fli1*, a transcription factor involved in vasculogenesis. The results of this study suggest that *M. koenigii* leaves contain potent angiogenesis inhibitors, which could be further characterized and developed as potent anticancer drugs.

Materials and Methods

Sample Collection and Extraction

The M. koenigii leaves were collected from in and around Mangalore. A thorough washing of the collected leaves was done with tap water followed by distilled water. The leaves were then air dried at room temperature for 48 to 72 hours, powdered, and were stored in an airtight container. Solvent extraction was performed following a previously described method.¹⁵ In brief, 10 g of dried leaf powder and 100 mL of the ethanol and water were added separately to 500 mL conical flask. It was kept in the shaking incubator at 37°C for overnight at 110 rpm. Following day, the suspension was taken from the incubator and filtered using muslin cloth and was poured into petri plates. These petri plates were kept at room temperature for drying. After drying, the extract was scrapped using spatula and was finely powered. The extract was then transferred into 15 mL conical tubes, and stored in 4°C. A 2,500 ppm stock was prepared by dissolving 25 mg extract in 25 mL solvent. It was than centrifuged at 12,000 rpm for 2 minutes. The filtrate was collected and used for exposure studies. For every trial, fresh stock was prepared and used.

Animal Husbandry and Rearing

Adult zebrafish were maintained at 28°C in a recirculating aquaculture system with 14/10-hour day/night light cycle. Embryos were generated by natural pairwise mating of adult fish.¹⁶ Breeding boxes were placed into the fish tank overnight. Embryos were collected in the morning and transferred into petri dishes containing embryo media (E3) and subsequently maintained at 28.5°C.

LC₅₀ Determination

A semistatic methodology, where media change with renewal of test compound twice a day, was followed. The experiments

Journal of Health and Allied Sciences NU Vol. 10 No. 2/2020

were performed in triplicates in microtiter plates with 10 embryos in each replicate. The embryos were exposed at 10-hour postfertilization (hpf) and mortality was recorded after 24 hours postexposure. To calculate LC_{50} , Kärber's method¹⁷ was employed where the concentration at which all the embryos were dead (LC_{100}) was considered as the upper limit and the concentration at which all the embryos survived (LC_0) was considered as the lower limit. Toxicity studies were conducted in accordance with OECD guidelines.

Evaluation of Developmental Toxicity of Aqueous and Ethanol Extracts

The developmental toxicity was evaluated for each of the concentrations. The experiments were conducted in triplicates with 10 embryos each. The embryos were observed for morphological changes for 5 days with change of water and renewal of test solution twice a day. The developmental stage at first exposure was the shield stage (10 hpf). Four types of toxicological assays, namely, developmental toxicity, cardiotoxicity, neurotoxicity, and hepatotoxicity were performed with observation and recording of lethal and sublethal end points. The effects on development was analyzed on day 1 postfertilization followed by cardiotoxicity on day 2, neurotoxicity on day 3, and hepatotoxicity on day 5. Data from three replicates for each end point for each concentration were recorded using a stereomicroscope at 10 magnification (Leica S9D, Germany) and were compared with the control (unexposed) embryos. The p-value was calculated using a *t*-test, and a value of <0.05 was considered statistically significant.

Assessment of Antiangiogenic Activity of Aqueous and Ethanol Extract

To investigate whether the extracts can prevent vasculogenesis in zebrafish embryos, transgenic zebrafish that expresses green fluorescent protein under the control of *fli* promoter (Tg [fli1: GFP]) was exposed to various concentrations of aqueous and ethanol extracts of M. koenigii leaves. Embryos (n = 10) in triplicates were exposed to various concentration of the compound at 10 hpf and were observed for the effects on intersegmental vessels (ISVs) and subintestinal veins (SIVs) at 48 and 72 hpf. A 10 µL of 1X phenylthiourea was added to all wells to prevent pigmentation. The embryos without exposure of the test compound served as control group. The microtiter plate was incubated at 28.5°C for the entire duration. For imaging, the embryos were anesthetized with tricane (final concentration 0.04%) and were photographed at 50 magnification using a fluorescent microscope (Leica DM2500, Germany).

Results

Developmental Toxicity of Aqueous and Ethanol Extracts

The toxicity of the test compound was determined by calculating the LC_{50} using the Kärber's method. As shown in **– Tables 1** and **2**, the LC_{50} of the aqueous extract was estimated to be 2,450 ppm and that of ethanol extract was 9.85 ppm. The results obtained from the exposure of aqueous extract indicated that the crude extract of *M. koenigii* leaves is quite safe without any significant mortality or developmental defects up to 1,000 ppm. At 1,500 ppm, mortality was observed for

Table 1 Estimation of LC50 for aqueous extract
--

Concentration (ppm) N = 30	Dose difference (a)	Mean death (b)	(a) × (b)
4,000	-	-	-
3,500	500	9.5	4,750
3,000	500	8	4,000
2,500	500	6	3,000
2,000	500	4.5	2,250
1,500	500	2.5	1,250
1,000	500	0.5	250
Total			15,500

Note: LC_{50} = Maximum dose ($\sum ab/no.$ of embryos used) = 4000 - (15450/10) = 2450 ppm.

 Table 2
 Estimation of LC50 for ethanol extract

Concentration (ppm) N = 30	Dose difference (a)	Mean death (b)	(a) × (b)
12	-	-	_
11	1	8	8
10	1	5	5
9	1	3.5	3.5
7	2	2.5	2.5
Total			21.5

Note: LC_{50} = Maximum dose (Σ ab/ no. of embryos used) = 12 - (24/10) = 9.85 ppm.

a few embryos, but it was not statistically significant. For concentrations ranging from 2,000 to 4,000 ppm, though the developmental effects were not evident at day 1, the effects of the extracts were quite apparent from day 2 onward and at higher concentrations, most of the embryos were dead by day 3 (**Fig. 1A**). Morphological defects including pericardial edema and incomplete yolk absorption were evident at concentrations beyond 2,000 ppm (Fig. 1B). Thus, the aqueous extract appeared to be nontoxic at concentrations up to 1,000 ppm. In contrast, the ethanol extract appeared to be highly toxic at concentrations beyond 11 ppm (**Fig. 2A**). At concentrations between 8 and 10 ppm, the embryos were unaffected with a few deaths at day 5. However, the reduction in number of live embryos was not statistically significant. Severe morphological defects including tail bending, lack of digestive system, and pericardial edema were observed beyond 11 ppm. The treated embryos did not survive till 5 dpf (► Fig. 2B).

Cardiotoxicity of Aqueous and Ethanol Extracts

To check the cardiotoxicity, the heart rate and rhythmicity were analyzed on day 2 postfertilization postexposure to both aqueous and ethanol extracts. The heart beat was calculated based on beats per minute and the values are represented as mean of three independent observations. In case of aqueous extract, there was no change in the heartbeat up to 1,000 ppm. However, the heartbeat decreased with increased concentrations and drastic reduction was observed after 3,000 ppm(> Fig. 3A). In case of ethanol extract, the treated embryos displayed a decrease in heart rate at 8 and 9 ppm. Intriguingly, the heartbeat was increased at 11 ppm onward (Fig. 3B), suggesting defective cardiac function. However, the looping of the heart was intact for both the extracts, even at higher concentrations, suggesting no effect on structural development of the heart in the treated embryos.

Fig. 1 Survival rate and developmental toxicity of zebrafish embryos treated with *Murraya koenigii* leaf aqueous extract.(**A**) Survival rates of zebrafish embryos treated with *M. koenigii* leaf aqueous extract at different days postfertilization. The embryos were exposed at 10-hour postfertilization (hpf) and the survival rates were recorded at 24, 48, 72 and 120 hpf. (**B**) Representative images of zebrafish embryos at 120 hpf exposed to different concentrations of aqueous extract: a–control, b–2,000 ppm, c–3,000 ppm, and d–3,500 ppm. Morphological anomalies such as incomplete yolk absorption (roundish yolk), pericardial edema (arrowhead), and reduced pigmentation were evident in treated embryos.

Investigation of Antiangiogenic Property in Murraya koenigii

To investigate the effects of M. koenigii leaf aqueous and ethanol extracts on angiogenesis, a transgenic zebrafish line that expresses GFP under the control of *fli1* was used. For determination of antiangiogenic activity, three concentrations below the calculated LC₅₀ (2,450 ppm for aqueous extract and 9.85 ppm for ethanol extract) that did not show any effects on embryonic development were chosen. As shown in Fig. 4, the exposure to the aqueous extract of M. koenigii leaves resulted in disruption of the ISV formation leading to defective ISVs (indicated by white box) at 1,000 and 1,500 ppm at 48 hpf (**Fig. 4A**). Although the effects on ISV formation at 48 hpf were marginal, at 72 hpf, it was more prominent with conspicuous absence of the proper branching of the ISVs in the treated embryos, particularly at 1,500 and 2,000 ppm, compared with the control (Fig. 4B). The aqueous extract also showed a severe effect on the SIV basket formation when observed at 72 hpf. As shown in \rightarrow Fig. 4C, in the control embryos (a), the SIVs were properly formed

with well-organized sprouting of the vessels in the form of a mesh-like structure (indicated by white arrow). However, in the treated embryos, there was either ectopic sprouting of SIVs or lack of SIVs suggesting an effect on SIV formation (**Fig. 4C**).

In case of ethanol extract, although the branching of the ISVs was not affected, the signal intensity of GFP was lesser in the treated embryos at 48 hpf (**► Fig. 5A**). However, at 72 hpf, there was no obvious difference between the treated and the control embryos (**► Fig. 5C**). Similarly, there was no effect on SIV formation in exposed embryos (**► Fig. 5C**).

Discussion

M. *koenigii* is known for its rich sources of carbazole alkaloids and have been used in traditional medicines because of its various biological properties.¹⁸⁻²⁰ The balance between proangiogenic and antiangiogenic factors describes the crucial process of angiogenesis. The imbalances in these factors contribute to impaired angiogenesis leading to vasculature

abnormalities which are exacerbated as tumor continues to grow.^{21,22} A promising strategy for cancer therapeutics could be exploring the antiangiogenic activity of the drug.²³ The present study focused on investigating the developmental toxicity and antiangiogenic potentials of *M. koenigii* leaf extract in vivo. Zebrafish model system has gained much attention in recent years as an in vivo model for angiogenesis study due to its physiological similarities with mammals.^{24,25} The results of this study showed that the aqueous extract of *M. koenigii* leaves are quite safe and the deleterious effects on development are visible only at high concentrations of 1,500 ppm and above. The developmental defects such as edema in heart, incomplete yolk sac absorption, and absence of swim bladder were observed in embryos when exposed to 2,000 ppm and above of *M. koenigii* extracts.

On the contrary, the ethanol extract appeared to be quite toxic and concentrations beyond 10 ppm interfered with the survivability of embryos beyond 3 dpf. Severe developmental effects such as body curvature, yolk sac burst, tail bending, and pericardial edema were observed at all doses and none of the exposed embryos could survive till 5 dpf. The developmental deformities observed in the present study are in concordance with the previous studies on toxicity and teratogenic effects of natural products such as curcumin and celastrol.^{26,27}

Characterization and screening of small molecules with antiangiogenic properties from natural sources have garnered wide attention in recent years. In this study, we have shown preliminary results of the effect of *M. koenigii* leaf extracts on vasculogenesis using transgenic zebrafish models. The results of this study indicated that the antiangiogenic activity of aqueous extract is more potent as compared with the ethanol extract. These observations corroborate the results shown in other studies conducted using natural products such as soya bean.²⁸ From our data, it is not clear why the aqueous extract alone demonstrated antiangiogenic activities. Antioxidant activity of aqueous extracts of M. koenigii could contribute to our observations. Indeed, a study on rats has shown that the aqueous extract of curry leaf can alleviate the cadmium-induced oxidative damage in cardiac tissues through its antioxidant activity.29

Conclusion

Although the data presented here are preliminary, they, nevertheless, demonstrate that the crude aqueous extract of *M. koenigii* leaves is less toxic and possesses antiangiogenic properties. In contrast, the ethanol extract is more toxic and does not show any antiangiogenic activity. The study also highlights the usefulness of the zebrafish model system as an effective in vivo tool for screening such natural compounds for their anticancer activities. Future work should be directed toward isolating the active ingredients from this crude extract and characterizing the active ingredients for its anticancer properties using mammalian systems.
