Abstract

Purpose Experimental models might help understand the pathophysiology of neurocysticercosis-associated hydrocephalus. The present study aimed to compare the extent of hydrocephalus and tissue damage in rats with subarachnoid inoculation of different concentrations of *Taenia crassiceps* cyst proteins.

Methods Sixty young rats were divided into two groups: low- and high-concentration groups. The animals in the low concentration group received 0.02 ml of 2.4 mg/ml *T. crassiceps* cyst proteins while those in the high concentration group received 0.02 ml of 11.6 mg/ml *T. crassiceps* cyst proteins. The animals underwent magnetic resonance imaging at 1, 3, and 6 months postinoculation to assess the ventricle volume. Morphological assessment was performed at the end of the observation period.

Results Repeated measures of ventricle volumes at 1, 3, and 6 months showed progressive enlargement of the ventricles. At 1 and 3 months, we observed no differences in ventricle volumes between the 2 groups. However, at 6 months, the ventricles were larger in the high concentration group (median = 3.86 mm³, range: 2.37–12.68) compared with the low concentration group (median = 2.00 mm³, range: 0.37–11.57), $p = 0.003$. The morphological assessment revealed a few

inflammatory features in both groups. However, the density of oligodendrocytes and neurons within the periventricular region was lower in the high concentration group (5.18 versus 9.72 for oligodendrocytes and 15.69 versus 21.00 for neurons; $p < 0.001$ for both).

Conclusion Our results suggest that, in rats, a higher concentration of *T. crassiceps* cyst proteins in the subarachnoid space could induce ventricle enlargement and reduce the number of neurons within the periventricular area.

Resumo

Objetivo Modelos experimentais podem ajudar a entender a fisiopatologia da hidrocefalia associada à neurocisticercose. O presente estudo teve como objetivo comparar a extensão da hidrocefalia e dano tecidual em ratos com inoculação subaracnóidea de diferentes concentrações de proteínas de cistos de *Taenia crassiceps*.

Métodos Sessenta ratos jovens foram divididos em dois grupos: grupos de baixa e alta concentração. Os animais do grupo de baixa concentração receberam 0,02 ml de proteínas de cisto de *T. crassiceps* (2,4 mg/ml), enquanto os do grupo de alta concentração receberam 0,02 ml de proteínas de cisto de *T. crassiceps* (11,6 mg/ml). Os animais foram submetidos à ressonância magnética 1, 3 e 6 meses após a inoculação para avaliar o volume do ventrículo. A avaliação morfológica foi realizada no final do período de observação.

Resultados Medidas repetidas dos volumes ventriculares aos 1, 3 e 6 meses mostraram aumento progressivo dos ventrículos. Após 1 e 3 meses, não observamos diferenças nos volumes ventriculares entre os 2 grupos. No entanto, aos 6 meses, os ventrículos foram maiores no grupo de alta concentração (mediana = 3,86 mm³, variação: 2,37–12,68) em comparação com o grupo de baixa concentração (mediana = 2,00 mm³, variação: 0,37–11,57; $p = 0,003$). A avaliação morfológica revelou algumas características inflamatórias nos dois grupos. No entanto, a densidade de oligodendrócitos e neurônios na região periventricular foi menor no grupo de alta concentração (5,18 versus 9,72 para oligodendrócitos e 15,69 versus 21,00 para neurônios; $p < 0,001$ para ambos).

Conclusão Nossos resultados sugerem que, em ratos, uma maior concentração de proteínas do cisto de *T. crassiceps* no espaço subaracnóideo poderia induzir o aumento do ventrículo e reduzir o número de neurônios na área periventricular.

Introduction

Neurocysticercosis (NC) is a common parasitic infection of the central nervous system (CNS) prevalent in Latin America, Sub-Saharan Africa, and Southeast Asia. Despite having a possibility of eradication, the disease remains endemic in communities with poor sanitary conditions and has reemerged in developed countries because of migratory flows.¹⁻³

The course of the disease is dependent upon the number of parasites, their stage of development, distribution within the brain, the subarachnoid space and the ventricles, and parasite-host interaction.⁴ In the extraparenchymal form of the disease, the cysts of the tapeworm *Taenia solium* lodge in the cerebrospinal fluid (CSF) compartments and may cause meningitis, vasculitis, hydrocephalus, and raised intracranial pressure.^{5,6} Hydrocephalus is one of the most devastating complications related to extraparenchymal NC. The high rate of infections and malfunctions of the ventricular shunts used to release hydrocephalus in patients with NC are the leading

causes of the considerably high mortality in these patients.⁷ Neurocysticercosis-associated hydrocephalus may occur due to obstruction caused by the presence of cysts at the narrow point of the CSF flow pathway within the brain ventricles, or due to inflammation within the subarachnoid cisterns.⁸⁻¹⁰

The pathophysiology of NC-induced hydrocephalus and the therapeutic options for the treatment of this condition are well-studied. However, the heterogeneity of the disease among different populations and age groups, mainly concerning the clinical presentation and the response to medical treatment, is poorly understood.¹¹ Experimental animal models of NC-induced hydrocephalus might help to address some of these issues.

Recently, we have developed a rat model of NC-induced hydrocephalus by cisternal inoculation of *Taenia crassiceps* cysts. In this model, we observed obstructive and inflammatory features that confirmed the successful induction of hydrocephalus.¹² However, the role of inflammation in NC-induced hydrocephalus is not yet studied. Since in clinical

practice, it is common to find patients with NC-related hydrocephalus without viable cysts, it might be possible that the degenerating cysts induce hydrocephalus. The present study aimed to assess whether cisternal inoculation of *T. crassiceps* cyst antigens in different concentrations could induce hydrocephalus and tissue damage of different severities.

Methods

Experimental Animals

Sixty male Wistar rats (*Rattus norvegicus*) aged 6 weeks were used in the present study. The animals were handled according to the current guidelines for the care and use of laboratory animals, and the local institutional review board approved the study project. The animals were kept under adequate sanitary conditions with food and water available *ad libitum*, in a room with a 12 h light/dark cycle under controlled temperature (21°C).

The animals were randomly divided into 2 groups: low ($n = 30$) and high concentration ($n = 30$) *T. crassiceps* antigens inoculation groups. The animals underwent magnetic resonance imaging (MRI) at 1, 3, and 6 months after the inoculation. After the 3rd MRI, the animals were euthanized and the brains were collected for histological assessment.

T. crassiceps Antigens Preparation

T. crassiceps cysts were maintained by subsequent inoculations in the peritoneal cavity of mice, where the cysts reproduce by gemmulation.¹³ The cysts were aseptically removed from the peritoneal cavity of mice and collected in beakers for immediate preparation of the antigenic suspensions. For the low concentration group, the cysts were resuspended in 100 ml of saline and for the high concentration group no diluent solution was added. The cysts suspension was sonicated with 60% amplitude at 10°C until a homogenous suspension was obtained. The resulting suspensions were centrifuged at 0°C and 180 Hz for 5 minutes and the supernatant was collected. The concentration of the protein in the suspensions was determined by the Bradford method. The protein concentration in the low concentration group was 2.4 mg/ml, and in the high concentration group, it was 11.6 mg/ml.

Inoculations

The rats were anesthetized with an intraperitoneal injection of 0.1 ml/kg mixture of ketamine (100 mg/ml) and xylazine (20 mg/ml). A 1-cm long skin incision was made at the occipitocervical junction, followed by blunt dissection of planes until reaching the skull, the posterior arc of the first vertebra, and the atlanto-occipital membrane. Next, 0.02 ml of the cyst suspension was injected with a 25-G needle between the occipital bone and the first vertebrae, through the atlanto-occipital membrane towards the cisterna magna. The skin was sutured with a 4.0 mononylon suture.

Magnetic resonance imaging

Magnetic resonance imaging was performed using a Vet-MR 0.25 T equipment (Esaote, Santo André, SP, Brazil). For MRI examination, the animals were anesthetized with 0.5 ml/kg of

the aforementioned mixture of xylazine and ketamine. The image acquisition protocol consisted of T2-weighted echo gradient acquisitions (slice thickness: 0.6 mm, echo time: 5 ms, repetition time: 10 ms) which provided a good visualization of the dilated ventricles, as previously described.¹² Ventricle volume was determined using ITK-SNAP version 3.0.0 software (GNU General Public License, Philadelphia, PA, USA) with a manual segmentation of the ventricles frame-by-frame. The investigator was blinded to the animal groups.

Morphological Assessment

After the 3rd MRI (6 months postinoculation), the animals were euthanized with an overdose of xylazine and ketamine. The animals were transcardially perfused with saline to wash out blood vessel contents, followed by 10% buffered formalin for tissue fixation. The brains were dissected out of the skull and cut in the coronal plane at the level of the optic chiasm. The samples were fixed in formalin overnight and then were dehydrated by transferring the tissue through solutions of increasing alcohol concentrations. Following this, the tissues were diafanized in xylene and embedded in paraffin. The blocks were sectioned into 5 µm thick sections and the sections were stained with hematoxylin-eosin. The morphological assessment was carried out using a morphometric approach using stereological point-counting, by which a uniform grid is plotted over the image and the points crossing the lines are counted.¹⁴ The morphometric approach considered the mean number of neurons, oligodendrocytes, astrocytes, vessels, inflammatory cells, and lymphocytes in the periventricular and ependymal regions.

Statistical Analysis

The distribution of data was assessed with the Shapiro-Wilk test. Differences between the groups were assessed using the Student t-test or the Mann-Whitney test. Differences in repeated measures within the same groups were assessed using the paired t-test and the Wilcoxon test. The Fisher exact test was used to compare frequencies. Differences were considered significant for p -value < 0.05. All statistical analyses were performed using IBM SPSS Statistics for Windows, version 21.0 (IBM Corp, Armonk, NY, USA).

Results

The perioperative mortality was 9 and 19 in the low and high concentration groups, respectively. Among the remaining 21 rats in the low concentration group, 4 died during the follow-up and 1 after the 3rd MRI. In the high concentration group, from the 11 remaining animals, 3 died during the follow-up period. Thus, imaging and histological assessment were performed on the remaining 16 rats in the low concentration group and 8 in the high concentration group.

Slight enlargement of the brain ventricles was observed in both groups postinoculation; the increase was more evident and significant in the high concentration group (► Fig 1), mainly at 6 months postinoculation. In the low concentration group, a significant increase was observed between 1 and 3 months postinoculation (medians 1.78 mm³ and 2.15 mm³,

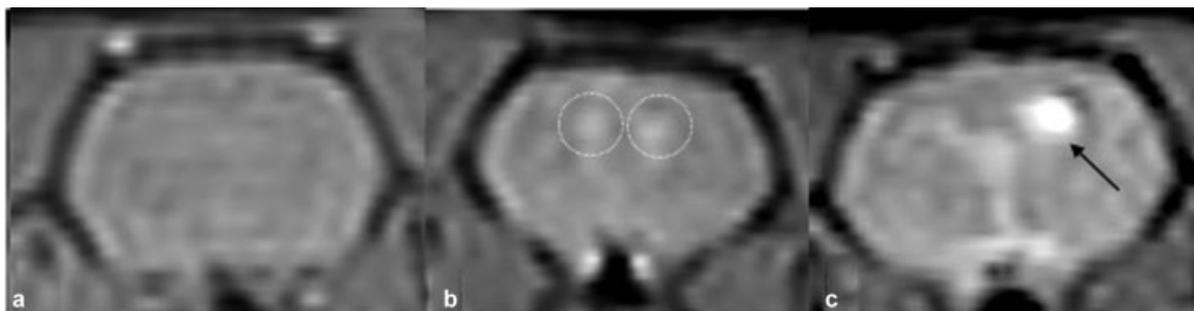

Fig. 1 Coronal magnetic resonance images (a) in the low-concentration group the ventricles cannot be visualized; (b) slight enlargement of the ventricles (dashed circles) in the high-concentration group; (c) an evident ventricle enlargement (arrow) from the high-concentration group.

Table 1 Ventricle volumes (mm^3) in the low- and high-concentration groups at 1, 3, and 6 months postinoculation

Month	Group	Average	Standard deviation	Median	Range	<i>p</i> -value
1	Low	1.67	0.85	1.78 [†]	0.30–2.82	0.180*
	High	2.64	2.25	2.04 [‡]	1.04–8.08	
3	Low	2.62	2.79	2.15 [†]	0.22–12.83	0.397*
	High	3.16	3.58	1.89 [‡]	0.45–11.20	
6	Low	2.63	2.52	2.00 [†]	0.37–11.57	0.003*
	High	5.26	3.35	3.86 [‡]	2.37–12.68	

[†]Wilcoxon test for repeated measures. In the low-concentration group, ventricle volumes were different at 1 and 3 months ($p = 0.032$), but not at 3 and 6 months ($p = 0.984$).

[‡]Wilcoxon test for repeated measures. In the high-concentration group, ventricle volumes were not different at 1 and 3 months ($p = 0.646$), but were different at 3 and 6 months ($p < 0.05$).

*Mann-Whitney test for independent samples. The ventricle volumes were not different between the two groups at 1 and 3 months, but were different at 6 months.

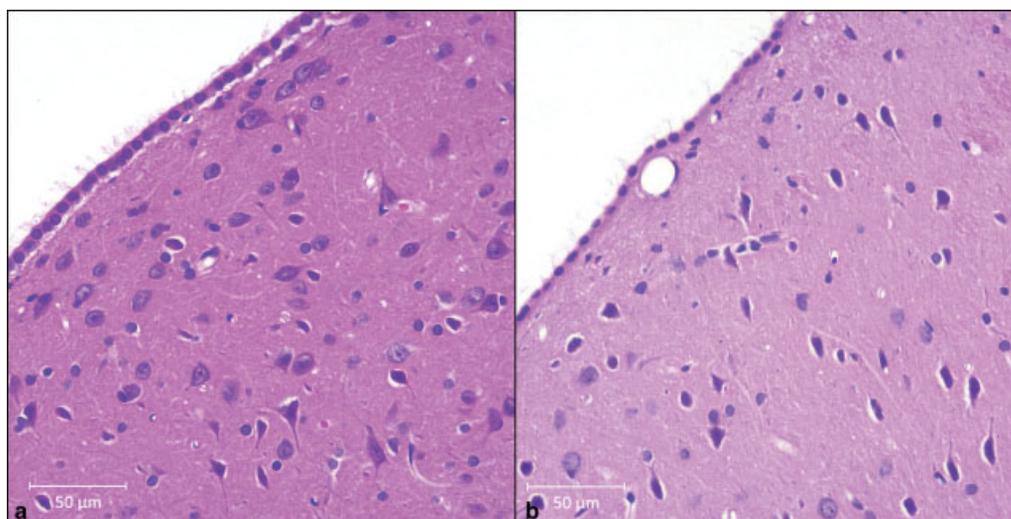

Fig. 2 Hematoxylin and Eosin staining of the brain sections depicting differences in neuronal density (a) the low-concentration group has a higher neuronal density compared to (b) the high-concentration group.

respectively), while in the high concentration group, a significant increase was observed between 3 and 6 months postinoculation (medians 1.89 mm^3 and 3.86 mm^3 , respectively) (**Table 1**). In the 1 and 3 months postinoculation follow-ups, the volumes of the ventricles were not different between the 2 groups ($p = 0.180$ and 0.397 , respectively). However, a significant difference in the ventricle volume was

observed between the 2 groups at 6 months postinoculation (medians 2.00 versus 3.86 mm^3 ; $p = 0.003$).

Morphological assessment revealed a few lymphocytes and new vessels in both groups. The ependymal lining was normal in both groups. The mean oligodendrocytes density was 9.72 and 5.18 in the low and high concentration groups, respectively ($p < 0.001$). Similarly, within the

periventricular area, a significant difference in the neuronal density was observed between the 2 groups (21.00 versus 15.69, low versus high concentration group, $p < 0.001$, ► **Figure 2**). Conversely, there was no significant difference in astrocyte density between the two groups (2.89 versus 2.74, low versus high concentration group, $p = 0.73$).

Discussion

Neurocysticercosis is a preventable, but an embarrassingly neglected infectious disease still prevalent in nondeveloped countries. It remains endemic in several countries in Latin America, sub-Saharan Africa, and Southeast Asia.¹⁵ Experimental animal models of neurocysticercosis are a valuable tool to study the characteristics of inflammation and the basic mechanisms underlying the heterogeneous relationship between the parasite and the host.¹⁶

In a previous study, we observed that, in rats, cisternal inoculation of antigenic suspension of *T. crassiceps* cysts induced a slight increase in the ventricle volume, without any signs of inflammation. We speculated that it was due to the low concentration of the inoculated proteins and that the inoculation of a higher concentration of antigens could induce a more intense inflammatory response, and more evident hydrocephalus.¹⁷ Herein, we observed that the animals who received a higher concentration of *T. crassiceps* cyst proteins had a significantly higher ventricle volume than those who received a low concentration of cyst proteins at 6 months postinoculation, confirming the previous hypothesis. In our experimental model, the induction of hydrocephalus at 6 month postinoculation is dependent on the presence of living cysts.¹⁷ The live *T. crassiceps* cysts might continuously recruit the inflammatory cells and obstruct the narrow passages within the ventricles; thus, a combination of inflammation and mechanical obstruction may lead to hydrocephalus.¹⁷ In contrast, the antigenic suspension form of *T. crassiceps* cysts may evoke a transient inflammatory response that may cause slight enlargement of the lateral ventricles without obvious hydrocephalus. It might be possible that inoculating the animals with even a higher concentration of cyst proteins may lead to hydrocephalus; however, further studies are required to prove this other hypothesis.

Another possible explanation is that this slight ventricle enlargement is due to a brain atrophy caused by the inflammation evoked by the response against the parasite. Actually, the intraperitoneal inoculation of *T. crassiceps* is able to impair the learning performance of mice, which is accompanied by hippocampal sclerosis. Apoptosis of hippocampal cells may be related to a breakdown of the blood-brain barrier determined by the presence of circulating *T. crassiceps* metacystode factor.¹⁸

Clinically, it has been well-documented that dead cysts may cause arachnoiditis, ependymitis, and hydrocephalus,¹⁹ which is one of the reasons for using corticosteroids to control inflammation during the antiparasitic treatment.²⁰ A few studies have cautioned about the risk associated with intraoperative rupture of *T. solium* cysts, which may lead to

ventriculitis^{21,22}; however, recent studies downplayed these risks.^{23–25} In the surgical management of hydatid cysts, the rupture of the cyst may worsen inflammation and lead to the seeding of infection.^{26,27}

In the present study, inoculation of the animals with a higher concentration of *T. crassiceps* cyst antigens failed to induce remarkable ependymitis and hydrocephalus. A possible explanation is that inoculation does not mimic the natural degeneration of cysts observed in humans. Further studies on cyst degeneration using antiparasitic drugs are required to conclusively prove this. Another possibility is the obvious differences between the parasites (*T. solium* versus *T. crassiceps*) and the hosts (human versus rat).

We observed no significant difference in the number of inflammatory cells between the two groups. Moreover, the number of lymphocytes was low in both groups. Since the histopathological assessment was performed at 6 months after the inoculation, the possibility of a transitory and self-limited inflammation that followed the inoculation within the first few days cannot be ruled out.

Interestingly, we observed reduced oligodendrocytes and neuronal density in the periventricular area of animals from the high-concentration group, which may explain the neuropsychological changes observed in patients with neurocysticercosis. The association between dementia and neurocysticercosis was demonstrated a few years ago; patients with neurocysticercosis may present changes in working and episodic verbal memory, executive functions, naming, verbal fluency, constructive praxis, and visuospatial orientation.^{28–30} Recently, another group with interest in experimental models of neurocysticercosis showed increased demyelination and hippocampal disorganization following intraventricular inoculation of *T. crassiceps* cysts.³¹ However, these animals also presented ventricle enlargement, which might have caused the observed morphological changes.^{32,33} In the present study, despite the low volume of the ventricles, the animals with a higher concentration of cyst antigens presented a reduced neuronal density. Further studies are required to investigate the link between neuroinflammation and neurodegeneration, as well as between neurocysticercosis and mesial temporal sclerosis, which has been extensively demonstrated in clinical studies.^{34–36} Besides, a recent clinical study has shown an interesting correlation between anti-brain protein autoantibodies and the levels of secreted *T. solium* glycoprotein HP-10, suggesting that the level of stimulation of the autoantibody response may be a function of the number of viable parasites.³⁷ This information adds evidence to the link between neurocysticercosis and neuroinflammation.

Finally, the present study has limitations. First of all, we did not use a control group without interventions. However, in our experience with previous experiments, we found that the inoculation of saline leads to no change on MRI and histologic assessments. Second, we could not precise the extent of inflammation soon after the inoculations because histologic assessments were done only at the end of the experiments. It is possible that the animals with larger ventricles and more histologic impairments had a more exacerbate initial inflammatory response, but we cannot be certain of this point.

In conclusion, we found that inoculation of a higher concentration of *T. crassiceps* antigens in the subarachnoid space of rats leads to a more remarkable ventricle enlargement and a significant reduction in the neuronal density within the periventricular area.

Conflict of Interests

The authors have no conflict of interests to declare.
