Thromb Haemost 2021;121:102–105.

Coronavirus disease 2019 (COVID-19) is characterized by severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) needing mechanical ventilation and intensive care unit (ICU) treatment. In addition to lung disease, clinical features of SARS-CoV-2 include myocardial damage and ischemia-related vascular disease, which are associated with a hypercoagulable state (e.g., high D-dimer levels) predisposing to thrombotic-related complications and eventually death.<sup>1–3</sup> Serum albumin levels <3.5 g/dL are detectable in SARS-CoV-2 patients and associated with death<sup>4</sup> and elevated D-dimer and thrombotic events,<sup>5</sup> which is in accordance with previous studies reporting an association between serum albumin <3.5 g/dL and risk of venous and arterial thrombosis.<sup>6</sup> Thus, we tested the hypothesis that albumin supplementation could dampen hypercoagulability in SARS-CoV-2 with serum albumin <3.5 g/dL.

This is an observational cohort study performed at a large university hospital located in Rome and Chieti (Italy) and devoted to COVID-19 care.

We included in the study adult ( $\geq 18$  years) patients with laboratory-confirmed COVID-19 and SARS-CoV-2-related pneumonia, requiring or not mechanical ventilation, consecutively hospitalized from May to September 2020. COVID-19 was diagnosed on the basis of the World Health Organization interim guidance.<sup>7</sup> A COVID-19 case was defined as a person with laboratory confirmation of COVID-19 infection, irrespective of clinical signs and symptoms. Oropharyngeal and nasopharyngeal swabs for laboratory diagnosis of COVID-19 were performed in duplicate: SARS-CoV-2 E and S genes were detected by a reverse transcriptase polymerase chain reaction.

The study included patients having high D-dimer, i.e., plasma values  $>1 \mu\text{g/mL}$ , and treated with prophylactic doses of low-molecular-weight heparin (LMWH;  $n = 10$ ) plus albumin supplementation ( $n = 10$ ); albumin supplementation was given intravenously at dosage of 80 g/day in the first 3 days and 40 g/day thereafter for a maximum of 7 days. Patients with high D-dimer treated with prophylactic doses of LMWH alone were used as controls ( $n = 19$ ). Demographic and clinical characteristics were collected after receiving informed consent. Routine analysis included coagulation tests (D-dimer, prothrombin time, activated partial thromboplastin time, and fibrinogen), serum albumin, and high sensitivity C-reactive protein (hs-CRP).

In both groups, D-dimer and serum albumin were measured at baseline and after 7 days of follow-up. During the intrahospital follow-up, thrombotic events and survival were registered as previously described.<sup>5</sup> Ethical approval for this study was obtained from Ethics Committee of Azienda Ospedaliero Universitaria Policlinico Umberto I with the agreement of Chieti University.

Statistical analyses were undertaken using SPSS 18.0 software for Windows (SPSS, Chicago, Illinois, United States). Between-group differences were analyzed by Kruskal–Wallis tests. The Wilcoxon test was used to assess the difference of the covariates before and after 7 days. Bivariate analysis was performed by the Spearman test. Differences between percentages were assessed by the  $\chi^2$ -test. A  $p$ -value of  $<0.05$  was considered statistically significant.

Characteristics of patients included in the study are reported in ► **Table 1**. No significant difference was observed

<sup>a</sup>Comparison between patients treated with albumin and controls (by Kruskal–Wallis tests).

<sup>b</sup>Comparison between patients treated with albumin and controls (by  $\chi^2$ -test).

<sup>c</sup>Comparison between values at baseline vs. after 7 days (by Wilcoxon test).

at baseline between albumin-treated patients and controls for age, gender, albumin, D-dimer, creatinine, hs-CRP levels, and clinical characteristics (►Table 1). Furthermore, there were no differences in the percentage of patients admitted to the ICU and medical wards (►Table 1).

At baseline, both groups had low values of serum albumin, approximately around 3.0 g/dL, and high values of D-dimer, approximately 3 µg/mL. The pairwise comparisons showed that only after albumin treatment D-dimer levels significantly

decreased (►Table 1 and ►Fig. 1); at the end of treatment, D-dimer was reduced by >50% in albumin-treated patients while no changes were detected in untreated ones. Conversely, serum albumin significantly increased in albumin-treated patients reaching, in average, values >3.5 g/dL. Bivariate analysis, performed by the Spearman test, showed that the absolute delta of albumin was inversely correlated with absolute delta of D-dimer ( $R_s$ : -0.440,  $p = 0.006$ ). During the hospital stay, a bleeding complication was registered in albumin-treated

**Fig. 1** Serum albumin and D-dimer levels in SARS-CoV-2 patients treated with albumin (A and B) and controls (C and D).

patients. A nonsignificant trend was observed for the occurrence of cardiovascular events between patients treated with albumin versus controls; a significant difference was observed for the number of deaths (– Table 1).

The study provides the first evidence that albumin supplementation dampens hypercoagulability in patients with SARS-CoV-2.

D-Dimer is a split-off product of fibrin degradation by plasmin and is, therefore, considered a marker of hypercoagulability.<sup>8</sup> Elevated levels of D-dimer are a frequent feature of SARS-CoV-2 and associated with an increased risk of thrombosis and death.<sup>2,3</sup> Hence anticoagulant treatment became a standard therapy for SARS-CoV-2 patients to reduce the thrombotic risk. Even if observational studies demonstrated that prophylactic as well as full dosage of anticoagulants improved survival in a population affected by SARS-CoV-2, the mortality was still elevated suggesting the need for identifying novel therapeutic strategies.<sup>9</sup>

Albumin is an acute-phase reactant, which is usually reduced in the case of acute and chronic inflammation, thus under normal physiologic conditions albumin exerts an antioxidant effect via an abundant source of free thiols that are able to scavenge reactive oxidant species (ROS).<sup>10</sup> In the case of oxidative stress, the Cys34 of albumin may undergo irrevers-

ible oxidation, which impairs its antioxidant property and eventually elicits cell and tissue damage.<sup>10</sup> It is interesting, in this regard, that albumin oxidation triggers neutrophil extracellular traps (NETs) via ROS accumulation within neutrophils, which eventually accumulate within lungs;<sup>10</sup> of note, accumulation of leucocytes and NETs has been detected in the thrombi detected in the lungs of SARS-CoV-2 patients.<sup>11–13</sup> Previous studies reported that albumin possesses antiplatelet and anticoagulant properties via a mechanism possibly related to its antioxidant effect.<sup>14</sup> In particular, albumin inhibits fibrin polymerization, enhances the effect of antithrombin III, and modulates the hepatic synthesis of factor V, factor VIII, and fibrinogen;<sup>15,16</sup> furthermore, albumin impairs platelet aggregation with a mechanism related to downregulation of Nox2, a powerful producer of ROS.<sup>14</sup> Others and we have previously reported a close inverse relationship between serum albumin and D-dimer suggesting hypoalbuminemia as a factor favoring hypercoagulability, thrombosis, and death.<sup>4,17</sup>

This hypothesis has been tested in the present study including patients with elevated D-dimer and serum albumin, in average <3.5 g/dL. We found a significant increase of serum albumin in albumin-treated patients coincidentally with a marked reduction of D-dimer, while no changes of D-dimer and serum albumin were detected in the control group. This

finding suggests that albumin exerts an anticoagulant activity in human, thereby its supplementation could turn useful in SARS-CoV-2 patients, in whom anticoagulant treatment, at least with a prophylactic dosage, seems to be unable to lower D-dimer; the coexistent low serum albumin could, perhaps, slow down clotting inhibition by anticoagulants. Unfortunately, however, our sample size does not permit drawing any inference regarding albumin supplementation and clinical outcomes; of note, however, we registered four deaths only in the control group. Even if this preliminary study is limited by a lack of randomization and inadequate sample size, it could suggest a novel therapeutic tool to counteract hypercoagulability in SARS-CoV-2 with elevated D-dimer and low serum albumin and warrants, therefore, further investigation by randomized clinical trials.

### What is known about this topic?

- Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) displays low levels of serum albumin which are associated with hypercoagulability and predict venous and arterial thrombosis.
- It is unclear if albumin supplementation is able to reduce hypercoagulability in SARS-CoV-2.

### What does this paper add?

- An observational prospective study performed in 29 SARS-CoV-2 patients treated with anticoagulant alone or anticoagulant plus albumin supplementation for 7 days demonstrated a significant decrease of D-dimer only in albumin-treated patients.
- Albumin supplementation may represent a novel tool to dampen hypercoagulability in SARS-CoV-2.

#### Authors' Contributions

F.V. designed the research and wrote the manuscript. P.P. wrote the manuscript. G.C., F.C., F.A., G.D'E, D.D., M.V., F.P., and C.M.M. performed the research. L.L. analyzed the data and wrote the manuscript. All authors reviewed the results and provided the final approval of the manuscript.

#### Conflict of Interest

None declared.
