

Total Synthesis of (+)-Monensin

Significance: In their landmark synthesis of the stereochemically complex polyether antibiotic (+)-monensin, published in three consecutive communications, Kishi and co-workers showcase elegant use of allylic strain as stereocontrol element.

Comment: Coupling of left and right half E and L was, after considerable experimentation, achieved by aldol addition using a magnesium amide base. Deprotection of benzyl ether M, ketal equilibration, and saponification gave the (+)-monensin sodium salt.
