A new technique for difficult biliary cannulation using endobiliary forceps in a patient with a periampullary diverticulum

An 83-year-old man attended the emergency room complaining of abdominal pain for 1 month. He had a history of having undergone cholecystectomy and had ongoing chronic kidney disease. His appearance was suggestive of chronic illness and there was tenderness on palpation of the right upper quadrant of his abdomen. On admission, the results of his liver function tests and blood chemistry were as follows: aspartate aminotransferase 31 IU/L, alanine aminotransferase 13 IU/L, total bilirubin 1.0 mg/dL, alkaline phosphatase 59 IU/L, γ-glutamyl transferase 12 IU/L, white blood cell count 4600 /mm³ (reference 3000 – 9000 /mm³), hemoglobin 8.2 g/dL, creatinine 3.42 mg/dL (reference 0.6 – 1.5 mg/dL), and albumin 2.5 g/dL. A non-enhanced abdominal computed tomography (CT) scan demonstrated a round calcified lesion of about 15 mm in size in the distal common bile duct (CBD) (▶Fig. 1).

Endoscopic retrograde cholangiopancreatography (ERCP) was performed with a side-viewing endoscope (TGF-240; Olympus Optical Corporation, Tokyo, Japan). A huge periampullary diverticulum was visualized; however, the ampulla of Vater was hidden inside the diverticulum (▶Fig. 2a). A prominent round lesion, presumed to be the ampulla of Vater, was noted at the 5-o’clock position. We failed to identify the ampullary orifice despite multiple attempts to expose it using suction, torque, or papilotome manipulation [1, 2].

A small-caliber endobiliary biopsy forceps (Olympus, Aomori Olympus Co., Japan) was inserted through the working channel of the endoscope. By grasping the mucosa with the forceps, we were able to pull the mucosa back out of the diverticulum and the ampullary orifice was eventually turned outward (▶Fig. 2b; ▶Video 1). After the orifice had been identified, the mucosa was secured with the forceps and a conventional cannula (Cook, Winston-Salem, North Carolina, USA) was then inserted through the same working channel, before being smoothly and successfully advanced into the bile duct (▶Fig. 2c). Following deep cannulation, a cholangiogram demonstrated a movable filling defect in the distal CBD (▶Fig. 3). The ductal stone was left intact and a 7-Fr plastic stent was placed into the bile duct over the guidewire (▶Fig. 4).

In the present case, we describe a simple but useful technique using a grasp-and-pull method as a rescue technique in a patient with an ampullary orifice that was facing inward from the rim of a diverticulum.

▶Fig. 1 A non-enhanced abdominal computed tomography (CT) scan image showing a round calcified lesion of about 15 mm in size (arrow) in the distal common bile duct.

▶Video 1 A periampullary diverticulum was seen, but the ampullary orifice was not visible. An endobiliary biopsy forceps was inserted through the endoscope to grasp the mucosa and pull it out of the diverticulum, thereby exposing the ampullary orifice. A conventional cannula was advanced through the same channel and the bile duct was successfully cannulated, with a plastic stent then being inserted over the guidewire.
