

## Endoscopic ultrasonography-guided photodynamic therapy for recurrent intraductal papillary mucinous neoplasm of the pancreas

Recurrence rates after partial pancreatectomy in patients with a noninvasive intraductal papillary mucinous neoplasm (IPMN) of the pancreas are reported as being 5.4% to 10.7% [1–3]. A recent case demonstrated the possibility of using photodynamic therapy (PDT) as an alternative therapeutic option for IPMN [4]. Herein, we present a patient who was treated with endoscopic ultrasonography (EUS)-guided PDT, which was used as an alternative, minimally invasive option for recurrent IPMN of the pancreas.

A 50-year-old man was admitted with recurrent pancreatitis. He had a history of distal pancreatectomy for combined-type IPMN 2 years previously, and the resection margins had been positive. A computed tomography (CT) scan revealed swelling of the remnant pancreas with a 13-mm hypodense lesion and prominent main pancreatic duct (MPD) dilatation. EUS-guided needle biopsy of a 5-mm nodular lesion in the MPD and a 15-mm hypoechoic mass in the stump demonstrated recurrent IPMN with low grade dysplasia (► **Fig. 1**). The patient re-

fused to undergo total pancreatectomy, so we decided to perform EUS-guided PDT (► **Video 1**) [5].

Photolon (a chlorin e6 derivative; Belmedpreparaty, Belarus) was administered at a dose of 2.5 mg/kg, 3 hours be-

fore the procedure. The flexible laser-light probe (a quartz core and polymer cladding; PhotoGlow Inc., Yarmouth, Massachusetts, USA) was preloaded inside a 19G EUS fine needle aspiration (FNA) needle (Cook Endoscopy, Winston-

Salem, North Carolina, USA) and was inserted into the recurrent tumor. The tumor was then illuminated with a wavelength of 660 nm (► **Fig. 2 a**). The energy dose was 100 J/cm of the diffuser length; the power of irradiation was 400 mW/cm of the diffuser length in each procedure. The total irradiation time in each needle pass was 250 seconds.

At follow-up EUS 2 years after the PDT, there was no evidence of recurrence (► **Fig. 2 b**). EUS-guided biopsy at the pancreas stump showed only acinar cells and interstitial fibrosis. The patient experienced no further episodes of pancreatitis during the follow-up period. This study was approved by the Institutional Review Board of Asan Medical Center (IRB number: 2015-0111).
