Re-intervention with endoscopic ultrasound-guided hepaticogastrostomy for unresectable hilar biliary drainage using a multipath occlusion balloon

Endoscopic ultrasound (EUS)-guided hepaticogastrostomy (EUS-HGS) and antegrade stenting (EUS-AS) have been developed as alternative biliary drainage methods; however, treating unresectable malignant hilar biliary strictures remains challenging [1–3]. We successfully performed re-intervention for malignant hilar biliary drainage after EUS-HGS using a multipath occlusion balloon.

A 46-year-old woman who was on medication for a postoperative recurrence of gastric cancer presented with jaundice. She had previously undergone double-balloon enteroscope (DBE)-assisted biliary drainage with a self-expandable metal stent (SEMS) for malignant biliary stricture of the lower bile duct. Contrast-enhanced computed tomography (CT) showed strictures of the hilar bile duct and duodenum (Fig. 1) associated with dissemination of the gastric cancer. EUS-HGS was performed (Fig. 2), and a 7-Fr plastic stent (TYPE-IIT; Gadelius Medical, Tokyo, Japan) was placed into the B3 bile duct [4]. However, the patient’s jaundice was not improved, and re-intervention was required. A 0.025-inch guidewire was placed into the duodenum beyond the papilla, and the plastic stent was removed. A second 0.025-inch guidewire was placed into the B5 bile duct using a multipath occlusion balloon (Bouncer; Cook Medical, Tokyo, Japan) (Fig. 3). This balloon has a multilumen located at either end of the balloon, which enables guidewires to be passed easily into crooked bile ducts (Fig. 3 and Fig. 4a; Video 1). A Zilver 635 biliary SEMS (Cook Medical, Tokyo, Japan) was introduced over the first guidewire and placed into the B5 bile duct, bridging the right and left hepatic ducts (Fig. 4b). Finally, a modified Niti-S GILOBR biliary stent (Century Medical, Tokyo, Japan) was placed into the B3 bile duct (Fig. 4c). The jaundice subsequently improved, and no adverse events occurred.
