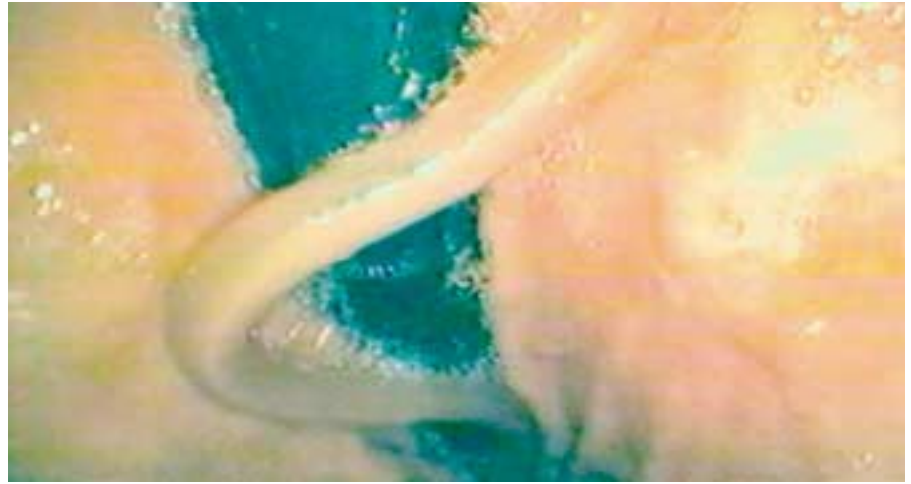

Figure 1 An 81-year-old Chinese-born man, with a history of lung cancer for which he had received both radiation and chemotherapy, underwent upper endoscopy for odynophagia. When the stomach was entered, a motile tubular structure with tapered ends and approximately 6 mm diameter and 20 cm length was noted. This had the appearance of *Ascaris lumbricoides*. The patient was treated with one dose of albendazole without effect on his symptoms.
