Mainz pouch II (modified ureterosigmoidostomy) is an established technique for permanent urinary diversion in patients with congenital malformations or acquired diseases of the bladder [1]. If urolithiasis occurs, an effective and minimally invasive therapy is mandatory. Extracorporeal shock-wave lithotripsy and surgical procedures are frequently used treatment strategies [2]. Retrograde endoscopic management is an alternative option, which has been reported rarely.

We report here the case of a 24-year-old man, who had undergone ureterosigmoidostomy at the age of 12 months due to bladder extrophy. The follow-up was unremarkable until the patient’s current presentation with acute right flank pain. The ultrasound examination revealed right-sided hydropnephrosis, and computed tomography identified a 6-mm ureteral calculus. During sigmoidoscopy, both ureteral ostia were located at a distance of 15 cm from the anal verge, with a normal macroscopic appearance. Urine drainage was identified only at the proximal ostium (Figure 1). The “dry” distal ostium was therefore intubated using a duodenoscope with a conventional endoscopic retrograde cholangiopancreatography (ERCP) catheter. A retrograde ureterogram was obtained by injecting contrast medium, revealing the 6-mm concrement in the distal ureter (Figure 2). A Dormia basket was inserted and the calculus extracted (Figure 3).

To our knowledge, this is the first reported case of successful extraction of a ureteral calculus using a duodenoscope in a patient with Mainz pouch II. Fitzgerald et al. report successful management of a ureteral calculus in a patient with ureterosigmoidostomy by retrograde sigmoid endoscopy with a 21-Fr cystoscope, in combination with intracorporeal lithotripsy [3]. Costamagna et al. successfully managed 19 of 24 ureteroileal complications in patients with ileal pouches using a duodenoscope. A ureteral calculus was removed in one patient [4].
Retrograde endoscopic management of ureteral calculi is thus a simple technique, which is minimally invasive and provides good access to the distal ureter in patients with ureterosigmoidostomy.
