

Endoscopic resection may be an appropriate alternative treatment in selected patients with ampullary tumors [1,2].

An 82-year-old woman was admitted for jaundice, fever, and right upper quadrant abdominal tenderness. Her medical history included a stroke, heart failure, and hypertension. Transabdominal ultrasonography showed a dilated common bile duct and pancreatic duct, with no evidence of biliary lithiasis, pancreatic tumor, or hepatic lesions. Endoscopic retrograde cholangiopancreatography (ERCP) demonstrated a prominent papilla of Vater suspicious for ampulloma (Figure [1 a]). Cholangiopancreatography also showed a dilated common bile duct and pancreatic duct, with a stenosis at the level of the sphincter of Oddi, but no intra-ductal tumor or stones.

After precutting of the papilla, a 10-Fr plastic biliary stent was placed, achieving effective drainage. Brush cytology and biopsy of the papilla showed a well-differentiated adenocarcinoma. Endoscopic ultrasonography demonstrated a well-demarcated 14-mm hypoechoic lesion at the papilla, limited to the mucosa and with no local lymph nodes (Figure [1 b]). The patient declined surgery, but accepted endoscopic resection, which was carried out under sedation with midazolam. Ablation of the tumor was accomplished using a standard polypectomy snare, exposing the pancreatic duct, with copious drainage of pancreatic juice. A 7-Fr stent was placed in the pancreatic duct to prevent pancreatitis. Pathological evaluation of the resected specimen confirmed a well-differentiated adenocarcinoma. The resection margins were free of tumor infiltration.

The patient was discharged 4 days after endoscopic treatment, and was asymptomatic, with normalization of laboratory values. The biliary and pancreatic stents were removed during an ERCP evaluation 1 month after the endoscopic ablation. Endoscopic follow-up examinations were carried after 2, 5, 14 and 24 months, al-

ways with biopsy and cytology, and no evidence of recurrent tumor was found. Endoscopic ultrasonography and magnetic resonance cholangiopancreatography carried out after 24 months also did not demonstrate any signs of tumor recurrence (Figure [2]). At the time of writing, the patient had been asymptomatic and without any abnormal laboratory values for a 24-month follow-up period.
