Endoscopic ultrasound-guided rescue of an uncovered self-expanding metallic stent causing biliary obstruction

Removal of a malpositioned uncovered Wallstent (Boston Scientific, Natick, Massachusetts, USA) can be extremely difficult, time-consuming, and associated with the occurrence of complications [1]. Stent extraction using standard polypectomy snare or rat-tooth forceps is often unsuccessful [1]. Alternatively stent removal can be accomplished by piecemeal extraction of individual stent filaments [1 – 4]. We present a case in which drainage of the biliary system, obstructed by a Wallstent wedged to the hilum, was achieved by endoscopic ultrasound (EUS)-guided puncture of the left intrahepatic bile duct followed by rendezvous endoscopic retrograde cholangiography (ERC).

A 57-year-old man with metastatic cholangiocarcinoma, who had undergone a previous ERC with placement of an uncovered biliary Wallstent, was referred to us for evaluation of persistent jaundice (bilirubin 58 mg/dl). A repeat ERC showed complete occlusion of the Wallstent, with some contrast spilling into the right biliary system and complete obstruction of the left system (Figure 1 a).

After multiple unsuccessful attempts at advancing a guide wire through the stent, the duodenoscope was exchanged for a linear-array echo endoscope (Olympus America, Melville, New York, USA), that was used to identify the dilated bile ducts within the left hepatic lobe and to puncture them using a 19-gauge needle. After bile had been aspirated and contrast injected to opacify the biliary system, a 0.035-inch Jagwire (Boston Scientific) was inserted through the needle and advanced antegradely across the mesh of the Wallstent (Figure 1 b). A rendezvous ERC was finally performed, with placement of a 6 cm long, 6 mm wide Zilver stent (Wilson-Cook Medical, Winston-Salem, North Carolina, USA) through the meshes of the Wallstent (Figure 1 c). Serum bilirubin levels were completely normalized 10 weeks after the procedure.

We have reported here an illustrative case of EUS-guided rendezvous biliary drainage; this approach can be considered as a valid alternative to the percutaneous transhepatic route when a malpositioned SEMS, not amenable to endoscopic removal, is the cause of obstruction.
