Human cysticercosis occurs when an individual with taeniasis brings his unwashed hands to his mouth (self-infection) or by the ingestion of contaminated food, water, fruits, and vegetables from orchards and gardens fertilized or irrigated with material that have been contaminated with Taenia solium eggs (hetero-infection). The increase of migration, immigration, tourism, and globalization also strengthens this dissemination. Neurocysticercosis (NCC) is globally spreading because infection of the taeniasis/cysticercosis complex is becoming widely endemic, particularly in the rural areas of Central and South America, Asia, and Africa. In accordance with the criteria of the World Health Organization, endemic regions for the taeniasis/cysticercosis complex are those regions where the contamination rate of the population is above 1% for taeniasis, 0.1% for human cysticercosis, and 5% for animal cysticercosis. In Asia, the endemic countries are China, Taiwan, India, Vietnam, Myanmar, Nepal, and the numerous islands of Indonesia. However, it is less common in Thailand, South Korea, Philippines, Malaysia, and Bangladesh.

Because of the communication difficulties arising from language and the wide discrepancies in the availability of laboratory resources, data on NCC incidence continue to be underestimated. The need to diagnose NCC, the knowledge of its epidemiology, and the natural evolution of the disease is often the only element available to most neurologists in developing countries.

In general, NCC is more frequent (51–80%) among males; however, female predominance (53–75%) has been observed, particularly in more severe manifestations. Deaths due to NCC range from 4.8 to 25.9% patients with NCC and in neurosurgery patients, this rate is 0–60%.

In the central nervous system, the cysticerci are fundamentally present in two forms [Table 1]: The simple larval form (Cysticercus cellulosae = CC) and racemose cysts (Cysticercus racemosus = CR).

One significant characteristic of NCC is the lack of a typical syndrome as we can see in Wiwanitkit and Wiwanitkit summary. May be asymptomatic, symptomatic or fatal; have an acute, sub-acute or chronic picture; or may be in remission or exacerbated. Moreover, neurological examinations are normal in 25–83% of patients. Rare manifestations are described in the literature like Parkinson’s syndrome always associated with the presence of CC and not to the CR, as reported by Wiwanitkit A and Wiwanitkit V. Asymptomatic form may be considered as a natural evolution of a clinical or sub-clinical manifestation, and its diagnosis may be an accidental laboratory or autopsy finding.
All clinical manifestations of NCC can mimic other pathologies, mainly infectious and parasitic diseases, which complicate diagnosis. The CSF may be normal, even in patients with viable cysticerci. Computed tomography and magnetic resonance imaging have allowed noninvasive diagnoses but can lead to false negatives.

In an attempt to standardize the diagnostic criteria of the NCC, diagnostic criteria were initially proposed in 1996 and revised in 2001, based on objective clinical, imaging, immunological, and epidemiological data.[6]

Treatment is a highly controversial issue. Based on the great differences in clinical presentation, pathogenesis, natural history, and treatment options for the different forms of NCC, a consensus of recommendations has been established.[7] Two drugs are commonly used praziquantel and albendazole. The choice of anti-inflammatory drugs includes steroids and dextrochlorpheniramine. Surgical treatment is still very controversial. Surgical removal has been recommended in cases of intraventricular cysticercosis and intraparenchymatous solitary giant cysts, provided there is no pericystic inflammatory reaction. The neuroendoscopic resection is the recommended procedure for intraventricular and subarachnoid basal cisterns cysts.[8] In NCC, shunts have frequent obstructions and may require multiple revisions. The recommendation is that this surgery must be performed before the introduction of cysticidal treatment.

The progression of NCC may be simple or complicated, have remission with or without treatment, and may exhibit symptoms that can disappear for long periods of time or persist until death. In other words, NCC may be asymptomatic, symptomatic or fatal; have an acute, sub-acute or chronic picture, or may be in remission or exacerbated.

Author Help: Reference checking facility

The manuscript system (www.journalonweb.com) allows the authors to check and verify the accuracy and style of references. The tool checks the references with PubMed as per a predefined style. Authors are encouraged to use this facility, before submitting articles to the journal.

- The style as well as bibliographic elements should be 100% accurate, to help get the references verified from the system. Even a single spelling error or addition of issue number/month of publication will lead to an error when verifying the reference.
- Example of a correct style
- Only the references from journals indexed in PubMed will be checked.
- Enter each reference in new line, without a serial number.
- Add up to a maximum of 15 references at a time.
- If the reference is correct for its bibliographic elements and punctuations, it will be shown as CORRECT and a link to the correct article in PubMed will be given.
- If any of the bibliographic elements are missing, incorrect or extra (such as issue number), it will be shown as INCORRECT and link to possible articles in PubMed will be given.
