Malignant melanoma of conjunctiva: Diagnosis on fine-needle aspiration cytology

Manjari Kishore, Vijay Kumar, Manju Kaushal

Abstract:
Malignant melanoma of conjunctiva is an uncommon malignancy. The diagnosis is suspected clinically and confirmed on pathological examination. We present a case of a 63-year-old female with previous history of pigmented lesion in the right eye and subsequently diagnosed as malignant melanoma of right conjunctiva and cornea on fine-needle aspiration cytology and histopathology.

Key words:
Conjunctiva, cornea, fine-needle aspiration cytology, melanoma

Introduction
Malignant melanoma of the conjunctiva arises from the malignant proliferation of melanocytes. It can arise de novo or from a preexisting nevus or primary acquired melanosis (PAM). Routine surgical biopsy of globe and deeply seated orbital lesions need aggressive procedures: anesthesia; and operating room. In comparison, fine-needle aspiration cytology (FNAC) is minimally invasive and much cheaper with fast results. We report a case of malignant melanoma of conjunctiva (right eye) on FNAC and confirmed on histopathology with encroachment over cornea.

Case Report
A 63-year-old female presented with pigmented and elevated lesion measuring approximately 0.8 cm × 0.8 cm, in the right eye for the last 1.5–2 years [Figure 1a]. Initially, the lesion had started as a thin black thread-like area; however, rapid increase in the size of lesion was noted in the past 1 month. Ocular examination revealed presence of cataract in both eyes with hazy corneal opacities. There was no difficulty in reading or vision. No blackish discoloration or such lesions were noted elsewhere in the body.

Her complete blood counts and biochemical parameters including liver and kidney function tests, serum electrolytes, blood sugar, and thyroid profile were within normal limits. B-mode ultrasound was done and a provisional diagnosis of a conjunctival lesion (? melanoma) with encroachment on cornea of the right eye [Figure 1b]. Her left eye showed evidence of macular hole.

Fine-needle aspiration (FNA) was done with extreme precaution under guidance of ophthalmologist. Eyeball was fixed using the ocular speculum, following which 22-gauze needle was inserted and minimal aspiration was done. Then, immediately gauze piece was put over the eye to give pressure and avoid any bleeding. FNA smears from the blackish lesion over right conjunctiva were highly cellular and comprised predominantly singly scattered tumor cells along with few groups and clusters [Figure 2a and b]. Tumor cells showed moderate pleomorphism and
Kishore, et al.: Conjunctival melanoma

were round to oval to spindle-shaped with central
to eccentrically placed nuclei, coarse chromatin,
prominent inclusion-like nucleoli, and moderate
amount of cytoplasm [Figure 2c and d]. Intracellular and
extracellular blackish-brown pigment (melanin) was seen
at places [Figure 2a-d]. Many binucleated, multinucleated,
and bizarre forms were also noted [Figure 2a-d].

Positron-emission tomography-computed tomography
scan showed mildly fluorodeoxyglucose (FDG) avid
enhancing soft-tissue thickening involving the right
anterolateral aspect of right globe, representing a
primary mitotic lesion. No evidence of FDG avid visible
mitotic disease was noted elsewhere in the body.

Based on the clinicoradiological and cytopathological
evaluation, a diagnosis of “Malignant Melanoma”
was given. The patient was referred to a higher
center for further surgical management. A wide local
excision was done with lamellar dissection of cornea.
Excised conjunctival mass showed features compatible
with malignant melanoma (epithelioid cell type with
ulceration of overlying conjunctiva) [Figure 3a]. The
tumor cells showed positivity for Melan-A [Figure 3b]
and S100 [Figure 3c], thereby confirming the diagnosis
of malignant melanoma. The excised margin showed
evidence of PAM with atypia. The separately sent lid
margin also showed evidence of malignant melanoma
along with features of PAM and atypia. A final diagnosis
of malignant melanoma of conjunctiva with extension into
the cornea as well as eyelid, including canthus (ICD-C43.1),
was made. Postoperatively, the patient was given
antibiotics (Tablet Augmentin) for 5 days along with
lubricant eye drops and is currently under follow-up.

Discussion

Melanoma is an aggressive tumor of the melanocytes.
Primary melanomas usually involve the skin, mucosa,
extracellular and intracellular pigment. Even the cases of amelanotic melanomas often exhibit coarse or fine-pigment granules in rare or a few cells which can be picked up on careful cytologic examination.

The cytologic diagnosis of amelanotic melanoma is difficult because in the absence of pigment, the tumor cells may mimic those of carcinoma or sarcoma in cytologic samples, particularly those obtained by FNA. Irregular nuclear outline and coarse chromatin are the features common to any of the malignant lesions, which are also applicable for melanoma cells. Of the general cytomorphic features elaborated above, intranuclear cytoplasmic inclusions are of diagnostic importance, only in conjunction with other cytomorphic and clinical features. Various disease entities such as papillary thyroid cancer, medullary thyroid cancer, and anaplastic thyroid carcinomas; bronchioloalveolar carcinoma, hepatocellular carcinoma, and renal cell carcinoma show intranuclear and cytoplasmic inclusion but can be easily differentiated with the help of clinic-radiological details.

In our case also, the patient had a pigmented lesion, PAM; however, the initial diagnosis was not made, and patient presented to us with increased blackish mass in the right eye encroaching over the conjunctiva and cornea. Conjunctival melanomas are potentially lethal, and they arise in association with preexisting PAM.\textsuperscript{[2-4]} Our patient also presented with similar findings with a history of PAM a year ago, and currently on admission, she had an increased blackish mass in the right eye. It is important to recognize and monitor precursor lesion owing to its malignant potential. It has been noted in few studies that malignant melanoma of eyelid with involvement of cornea and conjunctiva has poorer prognosis.\textsuperscript{[9-11]} Follow-up of suspicious conjunctival lesions by repeated biopsies may cause symblepharon, lid deformities, and discomfort to the patient.

The use of ancillary aids such as immunocytochemistry and electron microscopy is of critical value in the diagnostically challenging cases. Various immunohistohistochemical stains helpful in making diagnosis are S100, Melan-A, and HMB-45. Other differential diagnosis which should be kept in mind while evaluating these lesions are nevus, basal cell carcinoma, sebaceous gland carcinoma, Merkel cell tumor, or any metastasis. Hence, a detailed cytological and histological finding along with clinical correlation is important to differentiate these lesions.

Surgical excision along with adequate margins is the treatment of choice for melanoma.\textsuperscript{[8-11]} The prognosis of melanoma varies with the site and stage of the disease. Advanced disease with local recurrence or distant metastasis carries a grave prognosis.

**Conclusion**

Malignant melanoma of conjunctiva is a rare disease entity. The involvement of conjunctiva and cornea makes the prognosis poor. Hence, an early diagnosis of malignant melanoma is important to decrease the extent of disease and preventing any further complications in the patient. Although histopathology remains the gold standard in the definitive diagnosis of malignant melanoma, a simple investigative modality, that is, FNAC in conjunction with clinicoradiological findings can help in making an early diagnosis in the patient.

**Declaration of patient consent**

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.
