ABSTRACT

Objective: In permanent dentition, different rotary systems are used for canal cleaning and shaping. Rotary instrumentation in pediatric dentistry is an emerging concept. A very few studies have compared the efficiency of rotary instrumentation for canal preparation in primary teeth. Hence, this study was performed to compare the obturation quality and instrumentation time of two rotary files systems – Protaper, Mtwo with hand files in primary molars. **Materials and Methods:** Forty-five primary mandibular molars were randomly allotted to one of the three groups. Instrumentation was done using K-files in Group 1; Protaper in Group 2; and Mtwo in Group 3. Instrumentation time was recorded. The canal filling quality was assessed as underfill, optimal fill, and overfill. Statistical analysis was done using Chi-square, ANOVA, and *post hoc* Tukey test. **Results:** No significant difference was observed in the quality of obturation among three groups. Intergroup comparison of the instrumentation time showed a statistically significant difference between the three groups. **Conclusion:** The use of rotary instrumentation in primary teeth results in marked reduction in the instrumentation time and improves the quality of obturation.

Key words: Primary teeth, pulpectomy, randomized controlled trial, rotary instrumentation

INTRODUCTION

Pulpectomy is the choice of treating symptomatic decayed primary teeth and is a challenging and time-consuming procedure in pediatric dentistry.^[1] An efficient chemomechanical preparation is essential for effective canal disinfection and thereby contributes to the success of the endodontic procedure.^[2] Conventionally, hand files are used for cleaning and shaping and are time-consuming.^[3] The length of the appointment is strongly associated with the child's behavior.^[4] Removal of organic debris is the primary goal of canal preparation in primary teeth.^[5] Use

of rotary instrumentation for pulpectomy is an emerging practice in pediatric dentistry. The canals of the permanent teeth are prepared rapidly and uniformly with NiTi files resulting in superior obturation.^[6,7] Rotary instrumentation in primary teeth was advocated for its ability to provide conical-shaped canals and reduced the instrumentation time.^[3,8-11]

An *in vitro* study comparing the canal cleaning capacity of hand files, Mtwo and ProTaper showed no significant differences.^[5] Another *in vitro* study

compared the cleaning capacity and instrumentation time of K-files and Mtwo and concluded that there was no significant difference in cleaning capacity, but reduced instrumentation time with the use of Mtwo rotary system was evident.^[12] There are no *in vivo* studies in the literature comparing the manual instrumentation with Mtwo rotary system for pulpectomy in primary teeth.

Hence, the aim of this study was to comparatively evaluate the quality of obturation and instrumentation time using hand files, Protaper, and Mtwo rotary systems in primary molars.

MATERIALS AND METHODS

The randomized controlled trial was carried out in the Department of Pediatric and Preventive Dentistry in a Dental College from July to November 2016. The trial design was approved by the Institutional Review Board (STP/SDMDS2015PED42). The informed consent was obtained from the parents of the children participated in the study.

A total of 45 children aged 4–8 years requiring pulpectomy in any one of the primary mandibular molars were randomly allotted to one of the three groups where instrumentation was done using: Group 1: manual K-files; Group 2: proTaper rotary system; Group 3: Mtwo rotary system. Computer-generated randomization sequence was generated by a person, not involved in the study. The sample size was calculated from a previous *in vivo* study with 95% power using G Power analysis.^[13] The selection of the children was based on the following criteria: (a) vital or nonvital mandibular primary molars without sinus tract, (b) absence of internal or external pathologic root resorption, (c) presence of adequate coronal tooth structure to receive SS crown. The children lacking cooperative ability, children with underlying systemic diseases, and children with special health-care needs were excluded from the study.

All the procedures were done by a single operator. A full mouth examination with intraoral periapical radiographs of the teeth indicated for pulpectomy was taken before the start of the clinical procedure. After confirmation of the diagnosis, local anesthesia was administered using 2% lignocaine with 1:200,000 adrenaline (LOX* 2% ADRENALINE, Neon Laboratories limited, India). The tooth was isolated using rubber dam (GDC Marketing, India).

Using a round carbide bur in a high-speed handpiece, the superficial caries and roof of the pulp chamber were removed. Coronal pulp amputation was done with spoon excavator. No. 10 size K-file was used to determine the patency of the canals. The working length was determined with radiograph and was kept 1 mm short of the apex. The canal preparation was done using:

- Group 1: K-files from size 15 to size 30 in quarter pull turn method.
- Group 2: Only S2 ProTaper file was used till the working length using an X-Smart motor. (Dentsply India Pvt. Ltd., Delhi, India)
- Group 3: Only Mtwo file of 0.04 taper and 0.25 tip with X-Smart motor till the full working length (Dentsply India Pvt. Ltd., Delhi, India).

During the canal preparation, the instrumentation time was recorded in seconds using a stopwatch by an assistant. The canals were then irrigated with saline and dried using sterile paper points. The obturation was done using calcium hydroxide and iodoform paste by gently pushing with cotton pellets (Metapex, Meta Biomed Co., Ltd., Korea). A postobturation radiograph was taken to assess the quality of obturation. It assessed by another pediatric dentist who was blinded to the type of instrumentation used for canal preparation. The obturation quality was graded as underfill, optimal fill, overfill.

The glass ionomer cement (Shofu, Shofuinc. Japan) was given as the entrance filling. The pulpectomy treated teeth were restored with SS crowns either on the same day or in the next appointment.

The statistical analysis was done using SPSS software version 17.0. (Chicago, SPSS Inc). Chi-square test was used for inter- and intra-group analysis of quality of obturation. ANOVA and *post hoc* Tukey test were used for the compare the instrumentation time.

RESULTS

A total of 23 girls and 22 boys were participated in the study. The distribution of the participants is tabulated [Table 1]. Of 45 treated primary mandibular molars, 24.4% and 17.8% were mandibular left primary second and first molars, respectively. Mandibular right first and second molars comprised 28.9% each.

An intergroup comparison was done with respect to the age, gender, and distribution of the teeth using ANOVA and Chi-square test. No statistically

significant difference was noted between the groups with respect to the age ($P = 0.947$), gender ($P = 0.537$), and distribution of teeth ($P = 0.704$) indicating that there was an equal distribution of the participants and the teeth between all the three groups.

With respect to quality of obturation among the groups, in Group 1 (K-files): 60% of the mesial canals were optimally filled; 13.3% and 26.7% were under- and over-filled, respectively. In the distal canals, 40% were optimally filled, 26.7% were underfilled, and 33.3% were overfilled.

In Group 2 (Protaper): 73.3% of the mesial canals were optimally filled; 13.3% were under- and over-filled each. 60% of the distal canals were optimally filled; 20% were under- and over-filled each.

In Group 3 (Mtwo): 60% of the mesial canals were optimally filled; 33.3% were under-filled and 6.7% was over-filled. In the distal canals, 53.3% were optimally filled; 26.7% were underfilled, and 20% were overfilled.

Inter- and intra-group comparison of quality of obturation was done using Chi-square test. No statistically significant difference was observed in mesial ($P = 0.370$) and distal canals ($P = 0.823$) between the three groups [Table 2]. Between the mesial and distal canals, there was no significant difference in the teeth instrumented with K-file ($P = 0.218$). A significant difference was noticed between the mesial and the distal canals of the teeth instrumented with ProTaper ($P = 0.036$) and Mtwo ($P = 0.002$). The quality of obturation was superior in mesial canals than the distal canals [Table 3].

The mean instrumentation time is depicted in Table 4. Intergroup comparison was done using ANOVA and a statistically significant difference was noted between the three groups ($P = 0.000$) [Table 4].

Post hoc Tukey analysis confirmed that there was a significant reduced instrumentation time between the rotary and manual instrumentation [Table 5].

DISCUSSION

Early loss of primary molars is a serious issue of concern in pediatric dentistry. Pulpectomy should be the treatment option to maintain the integrity of facial tissue. Cleaning and shaping of the root canal is an important step in pulpectomy. The success of an endodontic procedure depends on the proper

Table 1: Distribution of the participants

	<i>n</i>	Mean age	Female (%)	Male (%)
K-file	15	5.60±1.121	53.3	46.7
ProTaper	15	5.60±1.183	40.0	60.0
Mtwo	15	5.47±1.506	60.0	40.0
Total	45	5.56±1.253	51.1	48.9

K-file	ProTaper	0.000
	Mtwo	0.000
ProTaper	K-file	0.000
	Mtwo	0.125
Mtwo	K-file	0.000
	Protaper	0.125

P<0.05, significant

mechanical debridement and obturation quality.^[14] There are many *in vitro* studies done in primary teeth comparing different rotary instrumentation systems with manual instrumentation.^[3,9-11] As there are no *in vivo* study done comparing manual files with ProTaper and Mtwo, this randomized, controlled, single-blinded trial was conducted to evaluate the quality of obturation and instrumentation time using K-file, ProTaper, and Mtwo.

ProTaper files are triangular in cross-section while the Mtwo files have S-shaped cross section. These files get engaged into the walls of the canals, producing smooth and tapered canal walls.^[15,16] Nagaratna *et al.* reported that the increased risk of instrument fracture

with rotary instruments is a potential limitation for its use in primary teeth.^[17] This is due to the softer and less denser root dentin, thinner and more curved roots with undetectable root tip resorption, and ribbon-shaped root morphology of the primary teeth.^[18] There are no clear guidelines for the sequence of using rotary files in primary teeth. Hence, a modified sequence of using only S2 file in ProTaper system and 0.04% taper with 0.25 tip of Mtwo rotary file was selected in this current study. This modified sequence combined with its use in a torque-limited handpiece resulted in no instrument separation within the canals.

With regard to the quality of obturation, there was no statistically significant difference between the groups in both mesial and distal canals. In the study done by Abbas Makarem in 2014 and Tania Ochoa-Romero in 2011, a statistically significant difference was noted in the quality of obturation.^[19,20]

Intragroup comparison showed superior obturation of the mesial canals in both rotary groups. The distal canals instrumented with rotary files were over obturated in majority of the cases. This could be due to the anatomy of the root canals. Distal canals are usually straight and wide while the mesial canals are curved and slender.

In the current study, a significant difference in the instrumentation time was noted between the three groups. The reduced instrumentation time was also evident in other studies done with different rotary systems.^[13,19] This decrease in the instrumentation time could positively influence the behavior of the child in the dental chair.

Inclusion of only the mandibular molars is considered as the potential confounder in the current study.

CONCLUSION

With the use of rotary instruments for pulpectomy in primary teeth, marked reduction in the instrumentation time has been appreciated resulting in decreased chair side time thereby positively influencing the child's behavior.
