

Resolution of Cytomegalovirus Pneumonia in a Child with Acute Leukemia Without Antiviral Pharmacotherapy; The Need to Tailor your Approach

Cytomegalovirus (CMV) pneumonia is one of the most common causes of respiratory distress in immunocompromised settings, including acute leukemia. Attributing a viral etiology to pneumonitis is difficult and is rarely attempted by clinicians outside the hematopoietic stem cell transplantation (HSCT) settings, especially in low and middle-income countries. This is mainly because of the nonspecific clinical picture, the absence of typical X-ray findings in viral pneumonia, and difficulty in demonstrating the virus in culture or doing a viral CMV polymerase chain reaction (PCR). The vital role played by the host immunity in determining the progress of CMV pneumonia cannot be neglected. There is a great need to tailor the approach towards the management of CMV pneumonia outside a HSCT setting, especially in cases with recovering immunity.

A 4-year-old boy with B-acute lymphoblastic leukemia on maintenance chemotherapy presented with acute-onset respiratory distress along with a fever of 2 days duration. At the time of admission, he was tachypneic with a respiratory rate of 56/min and hypoxic with a room air saturation of 77%. His chest X-ray was suggestive of bilateral pneumonitis [Figure 1] and his blood investigations revealed a total white blood cell (WBC) count of 0.9×10^9 cells/L with an absolute neutrophil count (ANC) of 0.2×10^9 cells/L. He was diagnosed as having febrile neutropenia with pneumonia and started on piperacillin-tazobactam, azithromycin, cotrimoxazole, and vancomycin, to provide coverage for the Gram-negative, Gram-positive, and atypical microorganisms including

Figure 1: Pneumonitis noted with involvement of both lungs in the form of diffuse reticular shadowing and patchy infiltrates

Pneumocystis jirovecii. Oseltamivir was also added considering the epidemic of H1N1 Influenza virus in the community. The chemotherapy medications (6 mercaptopurine and methotrexate) were withheld. With oxygen supplementation at 2 L/min, he maintained a SpO₂ of 98%. Considering the hypoxia, methylprednisolone was also started. As the fever persisted even after 96 h of admission, conventional amphotericin B was also added. On the 4th day of admission, his WBC count increased to 2.4×10^9 cells/L (ANC 1.5×10^9 cells/L), without the use of granulocyte colony-stimulating factors. His blood cultures never grew any organisms. His symptoms progressed in the form of worsening tachypnea and hypoxia requiring oxygen flow at 4 L/min. His repeat chest X-ray showed a diffuse infiltrative pattern with ground glassing. At this point, CMV quantitative real-time PCR was sent, and antibiotics were upgraded to meropenem. However, it was decided to withhold adding intravenous (IV) ganciclovir until disease confirmation or further deterioration. In the next 2 days, the child became afebrile and his general condition improved, except for minimal tachypnea and persistent hypoxia. We were unable to withdraw his oxygen support, even though he maintained a saturation of 98% with 1 L/min oxygen support. By the 14th day of admission, his CMV quantitative real-time PCR was reported as high positive (9.2×10^5 IU/ml, normal value <363 IU/ml); thus establishing the CMV etiology. As the child had already improved significantly, a bronchoscopic alveolar lavage to demonstrate CMV infection in the lungs/lung biopsy was not attempted. Furthermore, the consistent image of a diffuse interstitial pneumonitis on chest X-ray in the background of a very high positive CMV quantitative real-time PCR was highly suggestive of CMV pneumonia. On reporting positive for CMV infection, all his antibiotics and antifungals were stopped. The child was discharged on the 25th day of admission after restarting his maintenance chemotherapy. Awaiting the repeat CMV DNA PCR report and fearing for worsening of pneumonia, he was discharged on oral valganciclovir. At follow up after two weeks, valganciclovir was stopped as his CMV DNA PCR was reported to be normal (< 363 IU/ml).

Children with acute leukemia presenting to the emergency room with an acute respiratory distress are very common. Making a diagnosis of viral pneumonia is difficult, considering the lack of typical symptoms or signs. CMV is a common pathogen attributable to a viral

pneumonitis in immunocompromised settings, especially in HSCT recipients, in whom there is a high risk of mortality. In one Italian series, all untreated patients succumbed to the pneumonitis and its complications.^[1] Detection of viral antigen (pp65 antigenemia assay), viral DNA and mRNA are commonly used to confirm the diagnosis of CMV infection. Quantitative DNA detection techniques are highly sensitive and provide viral load measurements that can give important prognostic information. In the HSCT setting, intravenous ganciclovir along with immunoglobulins are used for treating CMV pneumonia. Although ganciclovir reduced viral load by 99% in the lungs of patients with CMV pneumonitis, there is no considerable reduction in mortality.^[2] The addition of immunoglobulins to IV ganciclovir has helped in reducing the mortality of CMV pneumonia considerably.^[3,4]

Although drugs are important in controlling CMV infection, the role played by the host immune system in combating CMV cannot be sidelined. CMV infection is controlled by virus-specific CD4 + and CD8 + cytotoxic T-lymphocytes through coordinated cytokine production and degranulation. CMV-specific immune reconstitution may be enhanced in children compared with adult HSCT patients due to improved posttransplant thymic function and faster T-lymphocyte recovery.^[5] Spontaneous resolution of CMV has been reported in adult patients with immunosuppression.^[6] Several studies show that the return of CMV-specific T-cell immunity leads to the control of and/or cessation of recurrences of CMV infection.^[7,8] Detecting the CMV-specific responses, Radha *et al.*^[7] noted that seropositive patients with substantial T-cell responses cleared CMV DNA rapidly along with antiviral therapy. Adoptive immunotherapy involving the transfer of CMV-specific T-cells into the patient has also shown promising results.^[9,10] Hence, in the management of CMV infection and disease, consideration should always be given to restoration of immunity, whenever possible.

The child in this report presented with febrile neutropenia and pneumonitis. He had continuous fever spikes initially and symptoms worsened by the end of the 1st week as his total WBC counts improved to 2.4×10^9 cells/L (ANC 1.5×10^9 cells/L) indicating an immune reconstitution inflammatory response. Although he recovered in a matter of few days, he was still oxygen dependent, indicating severe alveolar injury. It was exactly after 2 weeks of his start of symptoms that he could be weaned off oxygen support. By the time the quantitative CMV PCR was reported, the child had been weaned off oxygen support and had significant clinical improvement. We deferred adding IV immunoglobulin or IV ganciclovir at this point seeing his clinical improvement and also taking into account the natural course of CMV pneumonia. Addition of these drugs

would not have benefitted the child as he had already improved significantly. The role played by the body's immune system is clinically well appreciated in this case scenario, where the child had recovered without any specific antiviral pharmacotherapy.

The recognition and management of CMV pneumonia in immunocompromised patients, especially outside the HSCT settings are one of the most challenging situations to face. Tailoring your approach to the clinical situation and condition of the patient is pivotal in managing a case of CMV pneumonia rather than going for expensive diagnostic and treatment options, which, in many situations, are not really warranted.

Declaration of patient consent

The authors certify that they have obtained all appropriate patient consent forms. In the form the patient(s) has/have given his/her/their consent for his/her/their images and other clinical information to be reported in the journal. The patients understand that their names and initials will not be published and due efforts will be made to conceal their identity, but anonymity cannot be guaranteed.

Acknowledgments

We would like to thank Dr. Kusumakumary P, Former Professor and Head, Department of Pediatric Oncology, Regional Cancer Centre, Trivandrum and Dr. Ramachandran K, Professor and Head, Department of Imageology, Regional Cancer Centre, Trivandrum, for their guidance and support. We extend our gratitude to The Rajiv Gandhi Centre for Biotechnology, Trivandrum for conducting the Viral DNA PCR tests.

Financial support and sponsorship
