Abstract

Introduction: The guaiquica (*Gracilinanus microtarsus*) is an omnivorous-frugivorous marsupial, which belongs to family Didelphidae and subfamily Didelphinae. By feeding on small fruits, it is a species of considerable ecological importance in seed dispersal of some plants. The teeth are calcified and have adapted anatomical structures, which exhibit morphological variation among vertebrates. They are important for the systematic and sometimes represent the only traces of extinct species, and may also assist the phylogenetic reconstruction of these species. **Objective:** In order to establish morphological patterns of the teeth of *G. microtarsus*, the establishment of dental formula of the species was performed. **Materials and methods:** We used macroscopic analysis, microstructural analysis by light microscopy and ultrastructural analysis by scanning electron microscopy in five *G. microtarsus* adults (n= 3 males and n= 2 females) were performed. **Results and conclusion:** We conclude that the dental formula of *G. microtarsus* (2x I 5/4 C1/1 P 3/3 M 4/4), totaling 50 teeth is similar to that described in opossum (*Didelphis* sp.). The teeth are classified as thecodont and bunodont and microscopic morphology of teeth is also similar to *Didelphis* sp. and other species that have braquidonts teeth.

Keywords: didelphidae, digestory apparatus, marsupials, oral cavity.

1 Introduction

The guaiquica (*Gracilinanus microtarsus*), also known in Brazil as guaiquiquinha and catita are marsupials, which belongs to family Didelphidae and subfamily Didelphinae (LIMA, SANTOS, VIANA et al., 2013; LOBO, SANTOS, ROSA et al., 2014). This species presents white hairs at the ventral region and brown and gray hairs at the lateral and dorsal regions of body; black rounded spots around the eyes and small rounded ears; tapering and small snout and prehensile and hairless tail. It measures between 18 and 22 cm of length from snout to tail (CÁCERES, CASELLA, VARGAS et al., 2008).

It has omnivorous-frugivorous habits with varied diet consisting of insects, fruits and small vertebrates. By feeding on small fruits, it is a species of considerable ecological importance in seed dispersal of some plants (LOBO, SANTOS, ROSA et al., 2014), because it can moving long distances in the forests, then spreads together with their feces, the seeds of the fruits that ingests (FONTES, PASSAMANI, JACINTO et al., 2007).

Members of our research group have searched morphological correlations in organs of the digestive tract between different species of mammals such as the procyonidae *Nasua nasua* (SANTOS, BERTASSOLI, OLIVEIRA et al., 2010, 2012; SOUZA, OLIVEIRA, SANTOS et al., 2012) and *Procyon cancrivorus* (SANTOS, BERTASSOLI, OLIVEIRA et al., 2012; SANTOS, OLIVEIRA, VIANA ET AL., 2013); marsupials

as *Didelphis marsupialis* (CARVALHO, MANÇANARES, CASALS 2004; MANÇANARES, SANTOS, PIEMONTE et al., 2012); rodents as *Kerodon rupestris* (THOMAZ, CARVALHO, MIGLINO et al., 2006; SANTOS, ARO, BERTASSOLI et al., 2015); and between primates *Callithrix jacchus*, *C. penicillata* and *C. geoffroyi* (BERTASSOLI, SILVA, OLIVEIRA et al., 2013). Then, these morphological studies have been useful in phylogenetic comparison between species of different taxa.

The teeth are calcified and have adapted anatomical structures to collect, retain, cut, drill, tearing, crushing, grinding or milling the foods. They also have functions of attack, defense, movement and sexual courtship (BERTASSOLI, SILVA, OLIVEIRA et al., 2013). They are adaptable according to the feed habits of animals, and exhibit morphological variation among vertebrates. They are important for the systematic, because have permanent structure within the taxa (HILDEBRAND, 1995). Because teeth are hard and mineralized tissues, sometimes represent the only traces of extinct species, and may also assist the phylogenetic reconstruction of these species (DELLA-SERRA and FERREIRA, 1981).

In order to establish morphological patterns of the teeth of *G. microtarsus*, the establishment of dental formula of the species using macroscopic analysis, microstructural analysis

by light microscopy and ultrastructural analysis by scanning electron microscopy were performed.

2 Materials and Methods

2.1 Animals

Five *G. microtarsus* adults were used (n= 3 males and n= 2 females). The animals were fixed in 10% formaldehyde solution and kept in 70% ethanol solution. All animals were provided by Laboratory of Morphological Sciences at University Center of the Education Foundation Octávio Bastos with authorization from IBAMA (02001.007176 / 03-69).

2.2 Macroscopic and topographic analysis

The jaws of the animals were displaced to observation, description and counting of maxillary and mandibular teeth. The teeth were photographed with camera Sony Mavica 3.2mp. Then the teeth were removed for light and scanning electron microscopy (SEM) analysis.

2.3 Light microscopy

Molars, premolars, canines and incisors were processed by abrasive technique and observed under an optical microscope. Other samples were subjected to decalcification technique with a solution containing 800 mL of distilled water, 120 mL of formic acid and 80 mL of hydrochloric acid. After chemical decalcification materials were processed by routine technique of inclusion in paraffin. Then the material was cut into microtome Leica RM2165. 5 mm thick sections were stained with Hematoxylin/Eosin (HE). Photodocumentation was performed by light microscope Nikon E-400.

2.4 Scanning Electron Microscopy (SEM)

Samples of each tooth were dehydrated in ethanol at increasing concentration 50-100% and critical point Balzers CPD 020. Tissue fragments were fixed on metal supports (stubs) and then coated with gold ("sputtering" Emitech K 550). The analysis was performed by Electron Microscope Leo 435 VP.

3 Results

3.1 Macroscopic analysis and dental formula

The teeth have a portion embedded in the bone and an exposed part above of the gingiva. Ten maxillary incisors (I) and eight mandibular incisors were found. Diastema between the maxillary frontal incisors and lateral incisors and diastema between right and left mandibular lateral incisors were found (n = 18 I). Two mandibular and two maxillary canines (C) (n= 4 C) with diastema between them and the first premolars (P) were found. Six mandibular and six maxillary premolars (n = 12 P) with diastema between the first and second premolars and eight maxillary and eight mandibular molars (M) (n = 16 M) also were found (Figure 1). The dental formula was classified as $2x I 5/4 C 1/1 P 3/3 M 4/4$, totaling 50 teeth.

3.2 Light microscopy

The teeth were classified as braquidontes-type, in which the crown was covered by enamel above of the gingiva. The roots were inserted into the alveolar bone, united by periodontal ligament. Have layers of enamel, dentin with tubules and cementum and have crown and root with radicular channel.

The cement presented the cementocytes. The pulp was formed by blood vessels and nerves inside the loose connective tissue (Figures 2, 3).

3.3 Scanning electron microscopy

Two frontal maxillary incisors were found arranged next to the lip fissure and had a diastema between them and the lateral incisors, which had acute cusps with straight apex. The canine teeth had conical shape with more acute cusps those incisors. The premolars had less acute conical cusps that the canine teeth, but more acute than cusps of the incisors. The molar teeth had several cusps, which showed differences between the maxillary and mandibular teeth (Figure 4). On the molars was possible to observe the cusps, the roots, the crown, pulp, dentin, cementum and enamel (Figure 5).

4 Discussion

The absolute and relative dimensions of each tooth vary according to species. In individual animals teeth can vary according to age, level of specialization, vital occurrence and dimorphism. Simpler and more numerous teeth are found

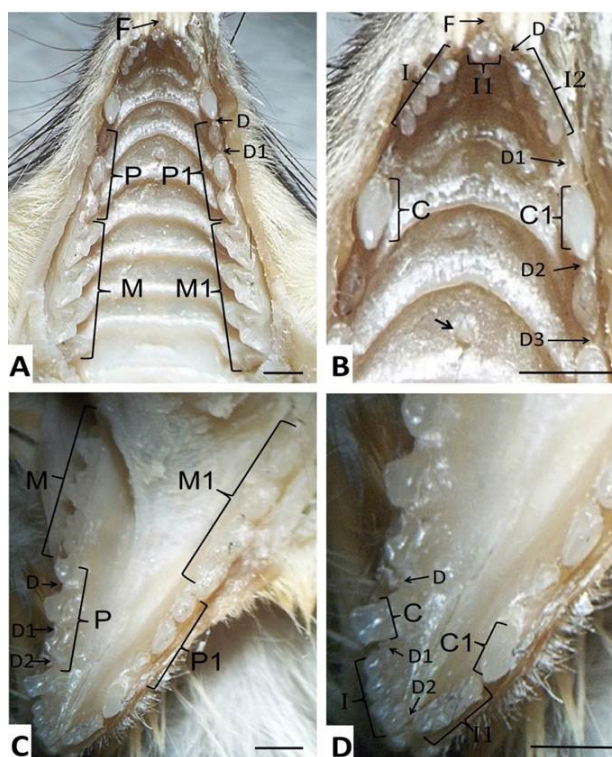

Figure 1. Maxillary (AB) and mandibular (CD) teeth of the *G. microtarsus*. (A) frontal incisors (F); premolars (P-P1); molars (M-M1); diastema between canine and first premolar (D) and between first and second premolar (D1). (B) lip fissure (F); diastema (D) between frontal (I1) and lateral incisors (I-I2); diastema (D1) between the lateral incisors (I-I2) and canine (C-C1); diastema (D2) between canine (C-C1) and first premolar; diastema between the first and second premolar (D3). (C) molar (M-M1); premolars (P-P1); diastema between canine and first premolar (D2) and between the first and second premolar (D1). (D) diastema (D) between canine and first premolars; diastema (D1) between lateral incisors (I-I1) and canine (C-C1) and diastema (D2) between the lateral incisors. Bars: 5mm.

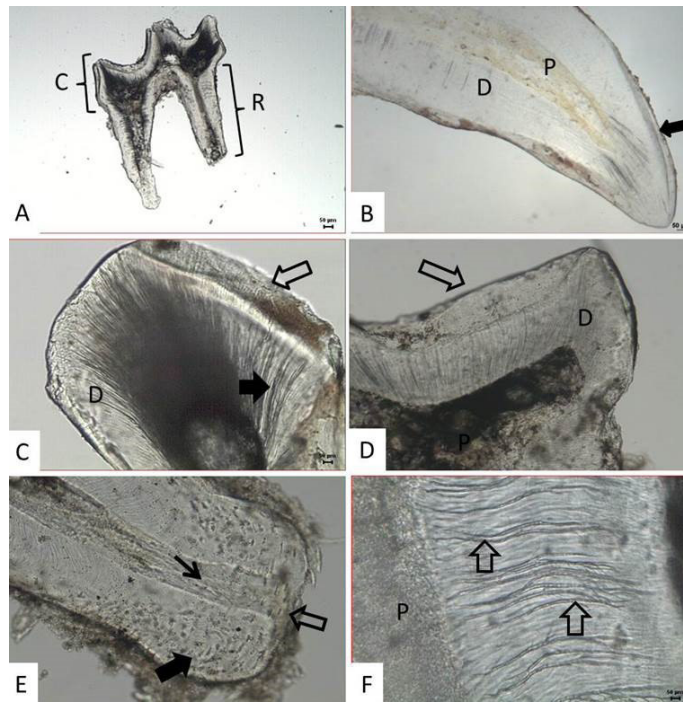

Figure 2. Photomicrograph of the teeth of *G. microtarsus*. (A) crown (C) and root (R) of the maxillary premolar. (B) Enamel (arrow); pulp (P); dentin (D) of the maxillary canine. (C) dentin tubules (full arrow); cementum (empty arrows) and dentin (D). (D) dentin (D) tubules (arrow) and molar pulp (P). (E) radicular channel (arrow); cementum (full arrow) and periodontal ligament (empty arrow) of the maxillary incisor. (F) pulp (P) and dentin tubules (arrows) of the maxillary incisor. Bars: 50µm. Abrasive technique.

Figure 3. Photomicrograph of the teeth of *G. microtarsus*. (A) apical foramen (arrow); root canal (filled arrow) of the periodontal ligament (star); alveolar bone (*) and dentin of the maxillary canine. (B) roots (R); cement (arrows); periodontal ligament (star); alveolar bone (*) of the mandibular premolar. (C) pulp (P); dentin (D); cementum (arrow), periodontal ligament (full arrow); alveolar bone (star) of the maxillary premolar. (D) cement (arrow); periodontal ligament (full arrow); pulp (P); dentin (D) of the mandibular canine. (E) cement (arrow); dentin (filled arrow); pulp (P); periodontal ligament (star); alveolar bone (*) of the maxillary incisor. (F) pulp (P); dentin (D) and dentin tubules of the maxillary molar. Bars: 50µm. Decalcification technique. HE staining.

in less phylogenetically complex animals while fewer and more complex teeth are found in more complex animals (DELLA-SERRA and FERREIRA, 1981). The change in the number of teeth in mammals is an adopted strategy to develop more specialized dentition, an important factor in the diversification of species (LINE, 2003).

The teeth of *G. microtarsus* had an inserted portion in the jaw and an exposed portion above gingiva, and this type of dental insertion is denominated thecodont. They are classified as bunodont due to masticatory surface is formed by different tubers with a rounded apex, as described in omnivorous Callitrichidae (BERTASSOLI, SILVA, OLIVEIRA et al., 2013)

Figure 4. Electromicrographs of the teeth of *G. microtarsus*. (A) frontal maxillary incisors (I); diastema (arrow) and lateral incisors (II). (B) mandibular lateral incisors (I) and canine (C). Bars: 300µm. (C) maxillary canine (C) and premolars (P). (D) mandibular canine (C) and premolars (P). (E) maxillary molars (M). (F) mandibular molars (M). Bars: 1mm.

Figure 5. Electromicrographs of the molar teeth of *G. microtarsus*. (A) cusps (full arrow); crown (C); root (arrow); pulp (*). Bar: 100µm. (B) Enamel (arrow); dentin (D); pulp (*). (C) enamel (arrow); dentin (empty arrows). (D) dentin (black arrow); cement (white arrow). Bars: 30µm.

and *Nasua nasua* (PIERI, MANÇANARES, BERTASSOLI et al., 2011). Present species has the dental formula $2x I 5/4 C1/1 P 3/3 M 4/4$, similar that found in *Didelphis marsupialis*, which also belong to the family Didelphidae (CARVALHO, MANÇANARES, CASALS et al., 2004).

In another study, members of our research group found similarity in the dental formula of *Callithrix jacchus*, *C. penicillata* and *C. geoffroyi*, and both species belong to the family Callitrichidae. In these three species dental formula was $2x I 2/2, C 1/1, PM 3/3, M 2/2$, totaling 32 teeth (BERTASSOLI, SILVA, OLIVEIRA et al., 2013). Rodents as *Kerodon rupestris* (THOMAZ, CARVALHO, MIGLINO et al., 2006) and *Chinchilla lanigera* (CROSSLEY, JACKSON, YATES et al., 1998) also have the same dental formula $2x I 1/1, C 0/0, P 1/1, M 3/3$, showing the importance of teeth in the systematic (HILDEBRAND, 1995).

Microscopically, the *G. microtarsus* have braquidont teeth composed of enamel, dentin, pre-dentin, pulp and periodontium as described in *Didelphis marsupialis* (CARVALHO, MANÇANARES, CASALS et al., 2004) and Callitrichidae (BERTASSOLI, SILVA, OLIVEIRA et al., 2013). After their formation, do not have continuous growth throughout life (BANKS, 1991). In Didelphidae, the teeth eruption sequence is similar in most species (TRIBE, 1990). The *Didelphis albiventris* have the onset of dentinogenesis around the third week after birth. The enamel begins to appear at this stage and will be deposited until the tenth week, and from that stage starts the maturation period (AZEVEDO and GOLDBERG, 1987). This process of formation, growth and eruption of teeth is influenced by several factors such as growth hormone, adrenal hormones, sex etc. (SASSAKI, DELBEM, SANTOS et al., 2003).

In *G. microtarsus*, similar to that described in *D. marsupialis*, the internal epithelium of enamel is composed of ameloblasts (columnar cells). The external epithelium of enamel is formed by small flattened cells. The pulp is formed by many blood vessels and nerves inside the loose connective tissue (CARVALHO, MANÇANARES, CASALS et al., 2004).

We conclude that the dental formula of *G. microtarsus* ($2x I 5/4 C1/1 P 3/3 M 4/4$) is similar to that described in opossum (*Didelphis* sp.); the teeth are classified as thecodont and bunodont; microscopic morphology of teeth is also similar to *Didelphis* sp. and other species that have braquidonts teeth.
